PUBLIC HEALTH REPORTS

Volume 68, Numbers 1-12
January-December 1953

including

PUBLIC HEALTH MONOGRAPHS

1953 Titles, Numbers 8-17

U. S. DEPARTMENT OF HEALTH, EDUCATION, AND WELFARE
Public Health Service

THIS ISSUE of the Index to *Public Health Reports* is divided into two parts. Part 1 is the index to *Public Health Reports* and Public Health Monographs. Part 2 lists the monographs published concurrently with the various issues of *Public Health Reports*.

Titles of original articles are followed by the author's name in brackets. Example: Treatment of tuberculosis [Amberson]-----928.

The author entries appear in capital and small capital letters followed by the title. Example: AMBERSON, J. BURNS: Treatment of tuberculosis-----928.

A monograph entry in part 1 carries a "see" reference to part 2 and can be found by referring to the specified monograph number in that part.

A code is used to indicate the other entry categories. Summary articles of monographs are indicated by (MS) following the entry; original articles interpreting a monograph by (MI). Other classifications used in the index are: (B) for briefs; (CR) for conference reports; (E) for excerpts; (LN) for legal notes; and (SR) for short reports.

Titles of current departmental publications appear under the entry "Publications" and are not cross indexed. A compiled annual list of Public Health Service publications may be obtained from the Public Inquiries Branch.

A cumulative manuscript file of the 1952 and 1953 indexes is available for consultation.

Since the illustrative material on the inside of the front cover is a part of the contents, it is recommended that the front covers of each issue be included when binding the volume.

American Public Health Association

1872-1873

ON THE 18th of April 1872, an informal conference of a number of gentlemen, who for several years had been in some degree co-workers in the studies of Preventive Medicine and in duties of public sanitary service, was held in the city of New York, with the design to secure concerted effort, and establish some adequate plans in the cultivation of hygienic knowledge, and procuring more effective applications of sanitary principles and laws. . . .

The first meetings of the Association have resulted in the cheerful contribution of reports and papers upon important sanitary questions, rather than in voluble debates; the rich fruit of careful observation and study, comprehensive surveys relating to epidemics and other diseases, and logically studied truths which are required for the basis and structure of true sanitary science and for the most effective methods and proceedings in public health administration. . . .

The golden maxim of Franklin that "Public Health Is Public Wealth," is obviously true in all communities, but the same maxim now finds a higher significance in the ascertained relationship of sound and vigorous health to the social and moral interests of individuals, families, and nations.

The chief problems of civilization and humanity now demand their solution upon a basis of most exact and compre-

hensive knowledge of facts reduced to the deductions and formulas of science, and it is not arrogating unreasonable functions for the principles and the public applications of sanitary science, to say that the physiological health of the people so far underlies soundness and sufficiency of mental culture that hygiene will have to be recognized as a fundamental element of success in common education and in the higher culture, as well as in the practical solution of the great social and moral problems of our times. . . .

In this volume of Sanitary Papers the records of two deadly epidemics—the fatal strides of cholera in the great valley west of the Alleghenies, and the invasion of Shreveport and Memphis by yellow fever when those cities were utterly defenseless, unguarded, and un-

The 117-bed King's Daughters' Hospital at Staunton, Va. (frontispiece and above). a community hospital built in 1951 with the aid of funds provided through the Federal Hospital Survey and Construction Act, replaced a 61-bed obsolete facility which had been operating at more than capacity under most difficult circumstances. Occupancy in the new building during the first year rose to almost 100 percent. However, the new hospital is planned for expansion: the kitchen, laundry, boiler room, and laboratory could take care of a 75-bed addition with only minor alterations.

As an intermediate hospital, the institution cooperates with the State's medical colleges in their intern and consultant programs. It also extends special services, particularly pathology, to many physicians in nearby communities and to the Waynesboro Community Hospital.

The Augusta - Staunton - Waynesboro Health Department is located in the hospital building, making for easier and closer association in its joint efforts with the hospital.

The hospital has attracted a number of additional physicians to the city and has had no staffing problems except in the nursing department. It has solved this problem, at least to a degree, through a practical nurse training program operated jointly with the local high school. In their senior year, selected applicants complete the academic phases of practical nurse training as approved by the State. They then join the hospital staff for the necessary in-service training. As students they help the professional nursing staff. Some of them remain with the hospital after completion of their training; and some go on to professional nursing schools.

The exterior (above) shows the main hospital building and main entrance, with the wing which houses the health department at the right.

On the frontispiece, one of the nurseries is shown at the upper left. At the center left is another view of the main entrance, and at the lower right a nursing station is shown. (Architects: York & Sawyer. Photographs by Sigurd Fischer.)

frontispiece . . .

Cancer research in the past 20 years and particularly since World War II has produced notable advances in both the treatment and diagnosis of cancer, despite the fact that it has yet to provide an all-purpose cure (see page 309). One of these advances is the development of the use of radioisotopes. Shown on the frontispiece is a technician holding a plastic block containing a beaker of radioactive phosphorous, one of a number of radioisotopes under study. The plastic material is dense enough to shield the technician from harmful radiation. Phosphorous has so far been used in whole body radiation and in the treatment of polycythemia vera and certain chronic leukemias. It has also been used, with limited success, as a tracer in the diagnosis of cancer of the brain, breast, and testicle.

The Challenge of the First Week of Life

IN LESS than four decades America has witnessed a reduction of more than two-thirds in its infant death rate. This saving in lives of infants has been achieved chiefly through the control of diarrhea and enteritis, and of pneumonia and influenza. The greatest saving has been in babies 1 week to 1 year of age.

Today mortality in the first week of life presents a primary challenge. In 1950, the infant death rate for the first week was 17.8 per 1,000 live births. Immaturity was reported as contributing to the deaths of 42,988 infants in 1950. The death rate per 1,000 live births in that year totaled 29.2. The rate for deaths associated with immaturity was 12.1. Immaturity as the sole factor in death was recorded for 22,413 infants.

To reduce this toll requires more good obstetrical care, special hospital facilities, and pediatricians and nurses with training in the care of premature babies.

When an infant is born prematurely and has to be separated from its mother, it is difficult to achieve the intimate relationship which ordinarily develops between mother and baby as she cares for it during the early weeks of life. When the mother begins to take care of her baby she may need help not only on how to feed and clothe the infant, but also in attaining a sense of security for herself and her baby.

Premature birth, however, is but one of the challenges to maternal and child health in 1953. For a discussion of both challenges and goals, see page 397.

Infant mortality rates by age,
birth-registration States, 1915-50

frontispiece . . .

The assault on poliomyelitis has many scientific facets. The disease is being investigated in the medical and public health laboratories, in the hospitals and medical centers, in the homes and communities where it appears. The inside cover picture symbolically represents some of the field approaches to the study of possible environmental factors in the transmission of poliomyelitis. In the Paulding County, Ohio, farmyard of a family of 5—with poliomyelitis diagnosed in 2 of the 3 children in 1950—are shown: an interviewer (far left) recording the family's medical history as given by the father; a physician and nurse drawing blood samples from the 3 children on the porch; a public health engineer (foreground) taking a water sample while another (rear, left) inspects an abandoned privy; an entomologist (center, stooping) counting flies on grill; behind him another entomologist hanging a light trap on windmill tower to attract other insects; and at right rear 2 veterinarians taking a blood sample from the family cow.

A review of morbidity trends in poliomyelitis in the United States, with special reference to the 1932-52 period, appears on pages 453-466.

Klickitat Valley General Hospital (center) was opened in December 1949 at Goldendale, Wash. For adequate hospital care before then, patients crossed the Columbia River—on an unscheduled ferry—to The Dalles in Oregon or traveled to Yakima, 81 miles away. The community had no physician.

The new 23-bed hospital is the first hospital completed in Washington State under the Hospital Survey and Construction Act (Hill-Burton program). Shown here are some of its well-equipped facilities.

A darkroom is adjacent to the X-ray room (lower left). The surgery (lower right) and obstetrical room share a high-powered, explosion-proof ventilating system to carry off anesthetic gases. The cheerful furnishings in each patient room (lower center) and the reception room (upper right) were do-

Goldendale's only hospital was this rented frame residence until 1949.

nated by Goldendale citizens. The new plant has almost a quarter of an acre of floor space.

Since the completion of its modern hospital, two young general practitioners have moved to Goldendale. Specialists in orthopedic surgery, gynecology, and radiology now come regularly from Yakima, The Dalles, and Portland, Oreg. The hospital cooperates with the local health department in sponsoring chest clinics.

Immediate financial success has accompanied the improved hospital service. The first year of operation showed a net gain of \$1,516. Admissions for 1952 totaled 1,042 as contrasted with the 700 patients admitted during the last year of operation for the old hospital.

frontispiece . . .

The new Tuberculosis Infirmary for Negroes at Sanatorium, Miss., represents an important forward step in the State's effort to control and eventually wipe out tuberculosis. It adds 154 beds in a thoroughly modern plant (top right) built with the aid of Federal funds under the State plan which is a prerequisite to participation in the Hospital Survey and Construction Program.

Among new adjunct facilities designed to help attract and keep good personnel are the nurses' home (center), the duplex houses for staff (lower right), and a dormitory for maintenance workers.

Since housekeeping, administrative, and maintenance operations were already provided for in older buildings, space in the new main building is devoted

almost exclusively to patient care facilities. Perhaps the most striking feature from the clinical standpoint is the eight-bed postoperative unit which occupies a wing on the second floor. It is a self-contained nursing unit equipped to give the specialized nursing care indicated immediately following a major operation.

The layout of the building shows facilities which are used jointly for in- and out-patients and are located conveniently to both types of patients. Numerous aids to patient comfort and rehabilitation are provided, including an occupational therapy and recreation department well above the average. (R. W. Naef, West Jackson, Miss., was the architect.)

Continued ►

I proudly dedicate this center to medical research as a symbol of our national concern for the health of our people, for their right to pursue happiness unhampered by crippling pain and illness.

In freedom, this building and the people who work here are dedicated to the endless struggle against human suffering.

We are dedicating it today—dedicating it to the open mind of research—dedicating it as an example of democracy heeding its obligation to free men, who, together, are self-governing.

—OVETA CULP HOBBY

WITH these words the Secretary of Health, Education, and Welfare on July 2, 1953, added a major resource to the public health and medical research potential of the United States of America.

Creation of the Clinical Center of the National Institutes of Health—research arm of the Public Health Service in the Department of Health, Education, and Welfare—is the latest in a train of developments which began in 1887 with the organization of scientific research endeavor by the then United States Marine-Hospital Service. In succeeding years, the focus of research was on major communicable diseases, and the methods were largely field epidemiology and laboratory study, basic and applied. The new Clinical Center permits an across-the-board approach via field, laboratory, and clinical routes. It facilitates, also, a coordinated effort against today's major and disabling diseases. "We have reached," Surgeon General Scheele said at the Clinical Center dedication, "a period of consolidation of forces for a broad attack on chronic diseases—an attack that can be fully successful only after years of intensive research. This means that we must not only press the search for new knowledge, but we must also use what we do know more intensively, more effectively."

Public Health Reports for September will report more fully on the dedicatory remarks of the Secretary and others and will present additional detail about the research program. For a description of the general philosophy and operating plans of the Clinical Center, see Public Health Reports, August 1952, pp. 819-823.

The spirit of the cooperative efforts of the United States of America and its sister nations to the south toward health and stability is epitomized in the language of the plaque, shown above, on the wall of the *Serviço Especial de Saúde Pública* hospital at Breves in the Amazon region of Brazil. The inscription under the initials M. E. S. (Ministry of Education and Health) reads:

*Special Services of Public Health
This building, symbol of the political understanding of good neighbor, was constructed by the governments of the United States of Brazil and of the United States of America*

Over the past 11 years, such expressions of mutual understanding have been repeated many times in many countries of Latin America, commemorating the health activities developed jointly by our own Institute of Inter-American Affairs and the ministries of the other American Republics. Some of these activities were described in *Public Health Reports* for April 1952, pp. 351-357. Beginning on page 829 of this issue, excerpts from the Public Health Service's evaluation, requested by the Institute of Inter-American Affairs, of the first 10 years of these international health undertakings are presented.

frontispiece . . .

In the upper photograph a visiting nurse is making her rounds among the families of La Paz, Bolivia. She was trained by and works for SCISP (*Servicio Cooperativo Interamericano de Salud Público*). At left, below, a nurse in a health center at Bogotá, Colombia, advises a mother and children on health maintenance. At right is a typical public fountain installation of a cooperative water supply project at Croix-des-Bouquets, Haiti.

Elements of Occupational Health Programs

An international group of experts jointly convened by the International Labor Organization and the World Health Organization in Geneva in 1950 agreed that "Occupational health should aim at: the promotion and maintenance of the highest degree of physical, mental, and social well-being of workers in all occupations; the prevention among workers of departures from health caused by their working conditions; the protection of workers in their employment from risks resulting from factors adverse to health; the placing and maintenance of the worker in an occupational environment adapted to his physiological and psychological equipment, and, to summarize: the adaptation of work to man and of each man to his job."

A second report of the group deals broadly with measures of general health protection of workers in places of employment, notification of occupational diseases, organization of health service programs in large and small plants and agricultural enterprises, and methods of cooperation between public health and industrial health services.

Recognizing that effective action requires "close cooperation with community health agencies working on parallel problems," *nutrition* of workers is seen as a concern of occupational health. Education not only of workers but of the housewife who prepares his meals is underscored. In the matter of *communicable disease control* the general objective everywhere is to detect cases and render them noninfectious. "This objective is especially important in industry, not only because there are hazards of infection of large numbers of persons in the working environment, but also because the place of employment provides valuable opportunities for the finding, treatment, and rehabilitation of cases."

Among *maternal and child health* considerations, "the protection of the health of pregnant women who are employed is of the first importance." The objective of *mental health* activities

is "to promote the health and happiness of people at work" and the way to do it is "not the provision of psychiatric services, but the planning of work tasks and patterns of industrial organization which do not run counter to human emotional needs."

Environmental sanitation is important for the prevention of spread of disease by water, food, air, or other means, and for avoiding the creation by industry of sanitary hazards for the surrounding community. *Health education* is a basic need, since "the effectiveness of all health service activities is directly related to the understanding and knowledge of the workers." *Nursing services* in the community "should be closely related to the medical service of the plant."

The general objective is to coordinate the official and unofficial services "so as to accomplish the largest volume of public health effort at a minimum expense to the community," such programs providing for "the complete cooperation on the local level of all the agencies having a bearing on the health of the worker."

—Joint ILO/WHO Committee on Occupational Health, Second Report. World Health Organization Technical Report Series, No. 66, July 1953.

frontispiece . . .

The insets symbolize the fact that research and service are two sides of the same coin of occupational health. New processes in industry produce new health problems requiring imaginative investigations. New developments in the medical and related sciences offer means of attacking old as well as new problems more effectively. In the September issue of Public Health Reports trends in air pollution control were examined. This month, the matter of occupational disease reporting is explored (page 940). Succeeding issues will report on other elements of occupational health, especially those relating to community and public health relationships.

The Scientific Team in Cardiovascular Research

The early disciples of Koch and Pasteur made significant advances using individual skills alone. Research today, however, looks to teamwork for the most consistent progress.

The "lineup" against the heart diseases, for example, may include investigators from many different disciplines, such as:

Anatomy	Hematology	Physical biology
Biology	Industrial hygiene	Physics
Biostatistics	Microbiology	Physiology
Chemistry	Nutrition	Psychiatry
Electrocardiography	Pathology	Rehabilitation
Electronics	Pharmacology	Roentgenology
Epidemiology	Physical anthropology	Social anthropology

At Public Health Service's National Institutes of Health, the research team of the National Heart Institute laboratory of chemical pharmacology calls upon many different skills in studying the fate of drugs in the body. Here the observations of the basic chemical and physical sciences are blended in developing methods for the estimation of drugs such as the barbiturates, local anesthetics, narcotic analgesics, dicoumarin-type anticoagulants, anti-inflammatory agents, sympathomimetic amines, and adrenergic blocking agents.

Electronic instruments, such as the spectrophotometer, may aid in measuring quickly and accurately as little as a millionth of a gram of a drug in a few drops of blood.

Involved in this laboratory and clinical study are biochemists, pharmacologists, physiologists, nurses, physicians, rehabilitation workers, roentgenologists, and others. Investigators may employ methods as old as science, along with modern radiochemistry. In the latter, the isotope labeling technique has been successfully applied, for example, to study the complete fate of pentobarbital in the body.

The goal in these studies is to find how certain drugs may be administered for maximum therapeutic effect, and to develop clues to more effective compounds, with blueprints for the synthesis of some of these. Chemical pharmacology is but one of the areas where research teamwork is advancing public health.

frontispiece . . .

In the upper left photograph, a doctor, studying under the research fellowship program of the National Heart Institute, observes the Van Slyke method of measuring the amount of gas present in blood samples. At upper right, investigators at the National Heart Institute laboratory of chemical pharmacology prepare apparatus for recording changes in blood pressure that result from use of experimental drugs. In the center, a young laboratory technician adjusts the chemical apparatus. At lower left, two research scientists discuss a cut-away model of the heart, while interpreting graphic findings related to heart physiology. At lower right, an investigator tests an experimental method of recording density changes and motions of the heart revealed by the electrokymograph.

Schistosomiasis

The parasitic worms which cause schistosomiasis, a chronic disease present in about 114 million individuals throughout the world, follow a complex life cycle, illustrated on the frontispiece. The disease is particularly widespread in areas of the world with low standards of sanitation. In some areas of Egypt, for example, 90 percent of the population suffers from schistosomiasis, and the productive potential of the nation is estimated to be lowered one-third.

The worms responsible for the disease are commonly known as blood flukes. They inhabit veins of the abdominal cavity and pelvis. The eggs extruded by the female worms penetrate various tissues and may find their way to all or nearly all organs of the body, where they cause inflammatory reactions and interfere with normal body function.

Various attempts to control schistosomiasis have included improved sanitation, mass chemotherapy, and attack on the snail intermediate hosts. The latter measure is one of the most promising, and in recent years attention has been focused on new chemicals which might be more effective. In many areas, transmission of the disease is intimately linked with age-old agricultural and religious practices, which are difficult to change. This, plus the fact that there is no satisfactory treatment for the disease, points to control of the snail hosts as one of the most promising approaches to the problem.

A debilitating affliction which often makes its victims too sick or too weak to work, schistosomiasis runs a chronic course which may extend over many years. Death may result from cumulative damage to vital organs.

During the last few years, chemicals which have proved effective in snail eradication experiments in the laboratory have undergone extensive field tests in various parts of the world by scientists of the laboratory of tropical diseases in the National Institutes of Health of the Public Health Service. One such project was set up in Recife, Brazil, in cooperation with the Pan American Sanitary Bureau and Brazil's Ministry of Education and Health. This work is reviewed by Wright and Dobrovolsky on p. 1156 of this issue of *Public Health Reports*.

spectator's reason for saying this. Recently, I have had occasion to dig into the story of public health in the past hundred years. As I picked up one thread after another and began to ravel it back to its origins, I found that Professor Winslow had been there before me as historian, as scientist, administrator, teacher, as prophet or philosopher.

Following such a leader, I find it difficult to bring you any original concepts of public health statesmanship. Nor does the subject lend itself to the closely reasoned development of a single theme, as would some technical aspect of public health. We are dealing instead with a kaleidoscope—the kaleidoscope of public health in the modern world. The same bits and pieces of modern society present themselves to us in an endless variety of patterns and problems. Our reflections, then, will be kaleidoscopic.

There is another difficulty. To discuss statesmanship is to discuss a human function. And it is a function fraught with the resolution of dilemmas, the making of decisions, and the exercise of wisdom, dedication, and leadership. These virtues are possessed in varying degree and are exercised consistently only by the uncommon man. Yet we of the public health profession must reflect upon statesmanship, must discuss it, and exercise it to the highest degree of which we are capable. For this is a period of history in which public health progress depends more upon the quality of our statesmanship than upon the specificity of our techniques.

I do not mean that our techniques are adequate to the solution of all our problems; nor that public health can relax for an instant its scientific effort for the discovery and development of better methods. Far from it. Nearly a century of organized public health work has proved the direct correlation of success with scientific advance and its resultant specificity of techniques. As public health progress has been based primarily upon the professional application of the biological and mechanical sciences in the past, so it will be in the future.

Nevertheless, the tide of events runs strongly in directions that should alert us to the challenge of statesmanship. America has entered a period of social evolution unlike any we have experienced hitherto.

The most obvious, and perhaps most potent,

difference is America's position of leadership in the free world—a leadership which carries heavy responsibilities affecting every phase of our society and economy. It has not been easy for us to endure with patience the effects of prolonged mobilization. It has not been easy for us to accept the urgency of our defense problems or to learn the art of persuading other peoples to the benefits of mutual security and the principles of democracy. These are new experiences for us; yet they are essential for survival in a world threatened by Soviet imperialism.

Socioeconomic Elements

The economy itself is working in unfamiliar directions. I say "unfamiliar" because many people forget that the depression of the thirties is 20 years behind us, and that the pattern for solution of public health problems in the future is likely to be different from that of the past 20 years. Reasonable pressure for economy in governmental health programs is one of those forces that "flow like a tide over communities only half conscious of that which is befalling them." This will constitute a major challenge to our statesmanship. Public health programs will grow; but we must study needs, set priorities, plan better, and work harder.

Moreover, unemployment has reached a new low since World War II and American industrial production in September reached the highest point since 1945. Entirely new technologies have been added, or have replaced many pre-war methods of production. Even more recent technological developments will bring about other changes in production. In agriculture, mining, and manufacture, the productive capacity of the individual worker has been more than doubled since the turn of the century. This enhanced productivity, coupled with the increased purchasing power of labor, has sustained a steadily rising standard of living. There is, for example, a startling difference in the variety and amount of foodstuffs which can be purchased today with a much smaller fraction of the workman's earnings, than 20 years ago.

The effects of these broad socioeconomic changes on public health are manifold, exceedingly complex, and ramiform. We may think

Public Health Statesmanship

By LEONARD A. SCHEELE, M.D.

I HAVE NOT the slightest hesitancy in announcing that I have plagiarized the title of this lecture: Public Health Statesmanship. It seems fitting, however, to inaugurate the Winslow Lectures with some reflections on this quality, this profession, this art of statesmanship—because Professor Winslow himself has exercised it in thought, word, and deed throughout his career.

In a symposium on Public Health Statesmanship at the University of Pennsylvania Bicentennial Conference in 1941, a symposium in which Professor Winslow participated, Dr. Parker Hitchens (1) quoted an unidentified passage which I wish to propose as the text of our discussion:

"History shows that great economic and social forces flow like a tide over communities only half conscious of that which is befalling them. Wise statesmen foresee what time is bringing and try to shape institutions and mold men's thoughts and purposes in accordance with the change that is silently coming."

This description of statesmanship gives us a good plumbline for our discussion. Note how it views the statesman as an embodiment of creative thought and action. Even the metaphor brings to mind a creative personality—

Dr. Scheele is Surgeon General of the Public Health Service. This paper, the first Charles-Edward Amory Winslow Lecture, was delivered at Yale University on November 14, 1952.

the potter, guided by his vision, shaping and molding the clay.

This description also asks us to ascribe historical perspective to the statesman as one of his essential qualities. And, finally, it gives a central position in the arena of statesmanship to the economic and social forces which ultimately shape the course of events.

Criteria of Statesmen

Creativity—historical perspective—and recognition of economic and social change: We need especially to emphasize these criteria in our consideration of statesmanship in public health. The members of the public health profession come from many scientific disciplines. As professional workers, we tend to place the highest values on our technical knowledge and skills. But as statesmen, we are challenged to be something more than good technicians.

As technicians, we are called upon day after day to apply our special competence to problems of bewildering complexity. As statesmen, we are challenged to learn whence these problems sprang, to trace their deep, far-reaching roots, and to learn how other men have viewed the health problems of their day. In public health, each man's sphere of direct action may be narrow—confined by the limited reach of his individual technology. As statesmen, we are challenged to see the inseparability of our sphere from the countless interacting forces of society—and, having seen, to think and act as statesmen.

Professor Winslow's response to this challenge is woven into the fabric of public health throughout the world. I have more than a

spectator's reason for saying this. Recently, I have had occasion to dig into the story of public health in the past hundred years. As I picked up one thread after another and began to ravel it back to its origins, I found that Professor Winslow had been there before me as historian, as scientist, administrator, teacher, as prophet or philosopher.

Following such a leader, I find it difficult to bring you any original concepts of public health statesmanship. Nor does the subject lend itself to the closely reasoned development of a single theme, as would some technical aspect of public health. We are dealing instead with a kaleidoscope—the kaleidoscope of public health in the modern world. The same bits and pieces of modern society present themselves to us in an endless variety of patterns and problems. Our reflections, then, will be kaleidoscopic.

There is another difficulty. To discuss statesmanship is to discuss a human function. And it is a function fraught with the resolution of dilemmas, the making of decisions, and the exercise of wisdom, dedication, and leadership. These virtues are possessed in varying degree and are exercised consistently only by the uncommon man. Yet we of the public health profession must reflect upon statesmanship, must discuss it, and exercise it to the highest degree of which we are capable. For this is a period of history in which public health progress depends more upon the quality of our statesmanship than upon the specificity of our techniques.

I do not mean that our techniques are adequate to the solution of all our problems; nor that public health can relax for an instant its scientific effort for the discovery and development of better methods. Far from it. Nearly a century of organized public health work has proved the direct correlation of success with scientific advance and its resultant specificity of techniques. As public health progress has been based primarily upon the professional application of the biological and mechanical sciences in the past, so it will be in the future.

Nevertheless, the tide of events runs strongly in directions that should alert us to the challenge of statesmanship. America has entered a period of social evolution unlike any we have experienced hitherto.

The most obvious, and perhaps most potent,

difference is America's position of leadership in the free world—a leadership which carries heavy responsibilities affecting every phase of our society and economy. It has not been easy for us to endure with patience the effects of prolonged mobilization. It has not been easy for us to accept the urgency of our defense problems or to learn the art of persuading other peoples to the benefits of mutual security and the principles of democracy. These are new experiences for us; yet they are essential for survival in a world threatened by Soviet imperialism.

Socioeconomic Elements

The economy itself is working in unfamiliar directions. I say "unfamiliar" because many people forget that the depression of the thirties is 20 years behind us, and that the pattern for solution of public health problems in the future is likely to be different from that of the past 20 years. Reasonable pressure for economy in governmental health programs is one of those forces that "flow like a tide over communities only half conscious of that which is befalling them." This will constitute a major challenge to our statesmanship. Public health programs will grow; but we must study needs, set priorities, plan better, and work harder.

Moreover, unemployment has reached a new low since World War II and American industrial production in September reached the highest point since 1945. Entirely new technologies have been added, or have replaced many pre-war methods of production. Even more recent technological developments will bring about other changes in production. In agriculture, mining, and manufacture, the productive capacity of the individual worker has been more than doubled since the turn of the century. This enhanced productivity, coupled with the increased purchasing power of labor, has sustained a steadily rising standard of living. There is, for example, a startling difference in the variety and amount of foodstuffs which can be purchased today with a much smaller fraction of the workman's earnings, than 25 years ago.

The effects of these broad socioeconomic changes on public health are manifold, exceedingly complex, and ramiform. We may think

of public health as a state of community well-being or as an institution created by society to protect and promote that state of well-being. Actually, it is both; but however we think of it, we are bound to recognize a continuously interacting relationship between the health of the people and the economy; and a similar reaction between public health practice and the society in which it functions. These interacting relationships determine in large measure the nature of our problems.

I have mentioned the kaleidoscopic patterns in which those problems present themselves. Yet there is an order and a unity of purpose in public health work which make it the great institution it is and which enable its disciples to serve the environing society with compassion, with dedication, and with a sense of partnership.

To understand this motivation, we do best to turn to a classic definition of public health which was formulated by Professor Winslow in 1920 and which has been so widely disseminated that it may now be called the charter of modern public health:

"Public health is the science and the art of preventing disease, prolonging life, and promoting physical health and efficiency through organized community efforts—for the sanitation of the environment, the control of community infections, the education of the individual in principles of personal hygiene—the organization of medical and nursing services for the early diagnosis and preventive treatment of disease—and for the development of the social machinery which will ensure to every individual in the community a standard of living adequate for the maintenance of health" (2).

Thirty-two years later, the Expert Committee on Public Health Administration of the World Health Organization adopted this definition as the basis of their discussions—with two minor changes which have a distinct Winslow flavor (3). They recognized an expanded concept of health education and changed "personal hygiene" to "personal and community health." Here at Yale, public health found

the early expression and practice of this modern concept of community health organization and education, as well as many of its first recruits to the new group of health educators trained in that concept.

The WHO committee also added this phrase: "so organizing those benefits as to enable every citizen to realize his birthright of health and longevity." We hear in those words the echo of many a plea by Professor Winslow for a higher level of health than the absence of disease and for the universal application of public health benefits.

In our charter, then, public health workers may find many opportunities for statesmanship both in our most familiar programs and in those less familiar. Let us consider a few of them.

Environmental Health

Control of environmental hazards is one of the oldest public health functions. With a few notable exceptions, which I shall refer to later, that effort has been directed to the prevention of communicable diseases. Many of the traditional sanitary practices of public health are now quite commonplace. In fact, they are too much taken for granted. Yet as they developed, in their time, many a public health pioneer, a public health statesman, fought uphill battles against ignorance and fear to gain better understanding and acceptance of public health practice in the community.

Americans are living in an environment quite different from that of 50 years ago—or, for that matter, even 10 years ago. Public health can no more ignore this new environment as a possible source of ill health than our professional ancestors could ignore the environment of their times as a source of devastating epidemics. Moreover, we now think of the environment in a wider dimension—to include social and psychological factors along with the physical. The incidence of fatal and disabling accidents, for example, calls for the study of all these factors. The relationships of environment with mental health and such chronic ailments as heart disease, cancer, arthritis, and rheumatism also must be investigated.

Public health statesmanship requires that we recognize the health components in the new

environment. Often they go unchallenged, not only by the persons directly concerned with creating new environmental situations, but also, regrettably, by public health personnel.

The Chemical Environment

None of us, for example, can escape the influence of chemicals on our daily living. For the most part, that influence has been beneficial to a high degree. But in the field of public health, we are beginning to see clouds upon the horizon, literally. The problem of air pollution is no longer confined to our work places or to our largest industrial centers, but is a potential threat to health even in semirural communities where industries, domestic heating systems, and climatic conditions combine to produce serious "smogs."

It is significant to our reflections on public health statesmanship that in 1912 the New York State Commission on Ventilation, of which Professor Winslow was a distinguished member, was appointed by the governor at the request of the New York Association for Improving the Condition of the Poor. The association put up \$50,000 for the work of the commission, especially in investigations of the relation of ventilation in tenements and schools to ill health.

In 1949, it was a local labor union that requested the Public Health Service to make a thorough study of the smog in Donora, Pa. Since that time, a number of community organizations have sought help in studying their air pollution problems.

Is it a measure of public health statesmanship that 40 years ago and again 3 years ago, it was not the official health agencies, but members of the society in which they function, who sought action in studying the health component of air pollution? If public health workers do not see beyond the performance of their prescribed routines; if they do not recognize the health implications of the new environment nor bestir themselves to interpret the problems to society, then we can say that their statesmanship in environmental health does not measure up.

Public health knowledge of chemical and radiation hazards began with the study and control of occupational diseases. Today the number of known substances, compounds, and

processes used in industry runs into the thousands and is being increased day by day. To what extent the industrial uses of chemicals and radioactive substances affects the health of the general population is not known with anything like the specificity of our knowledge of occupational hazards.

The addition of chemicals to many processed foods and the development of new physical techniques for the preservation and transportation of foods also require study. The Select Committee of the House of Representatives to Investigate the Use of Chemicals in Foods and Cosmetics held extensive hearings in the 82d Congress and it is clear from the committee's report that more research is needed to determine the effects of chemicals in foods on human health. It is not clear, however, what the relationships between government and industry should be in the conduct of such research and in the formulation and enforcement of standards. Here is another instance in which statesmanship is, at the present time, more important for solution of the problems than the specificity of existing science.

Water Resource Problems

The pollution of our inland waters by industrial wastes is one of the largest domestic problems facing this country. It involves our total economy and is a present threat to industrial expansion, agriculture, recreation, fish and wildlife, and public health. We are still far from understanding the new types of pollution, as well as from solving this growing problem. During the past 4 years, the Public Health Service has worked with State and interstate water authorities and industrial groups to stimulate research. We are cooperating also with the Atomic Energy Commission in studies of the disposal of radioactive wastes. The current work, however, on both chemical and radioactive pollutants is only a small beginning of what is destined to become a large field of public health research and control.

Statesmanship in this field requires involving all the interested groups. For public health workers, it also provides a fine opportunity not only to interpret the health component in water pollution to persons primarily concerned with some other problem, but also to recognize and

The Winslow Lecture

Dr. C.-E. A. Winslow (right) and Dr. Ira V. Hiscock (left), chairman of the department of public health at Yale, with Dr. Scheele on the occasion of the first of the annual lectures sponsored by the Yale public health alumni in honor of Professor Winslow.

Dr. Winslow is the Anna M. R. Lauder professor emeritus of public health at Yale and editor of the *American Journal of Public Health*. After training with Sedgwick, and with wide experience, he joined the Yale faculty in 1915 as chairman of the department of public health, retiring in 1945 after 30 years of service, during which he achieved international recognition as leader, teacher, and exponent of public health. In 1942 he received the Sedgwick Memorial Medal of the American Public Health Association "for distinguished service in public health." In 1952 he received a special Lasker Award from the Association, and the World Health Organization conferred upon him the Leon Bernard Foundation prize.

interpret the common interest of many diversified groups in the development and conservation of the Nation's water resources.

One of the valuable lessons we have learned is the greater efficiency of a team approach to the water resources problem. The team that public health statesmanship seeks, of course, is not a group composed solely of collaborating Federal agencies, but rather a group in which State agencies and others are fully participating members.

I cannot leave the problems of our chemical environment without reference to the fluoridation of public water supplies as a means of preventing dental decay. This is probably the first and only instance in public health to date in which a "mass sanitation" technique has been developed for the prevention of a noncommunicable disease.

The epidemiological studies of fluorine in natural water supplies and of artificial fluoridation have been classics. We in the Public Health Service have every reason to be proud of the work of some of our men in this field. Time will prove that this single discovery and development has been one of the great contributions to human health.

Like all innovations, fluoridation has met

with resistance. And it is this very resistance that calls for statesmanship. In responding to something new, people forget facts long since accepted. They forget, for example, that fluorine exists in small amounts in many animal and plant tissues such as are found in the average diet, as well as in many natural waters. We have had varied reactions, from enthusiastic acceptance to uncertainty about the ingestion of fluorine, and even unfounded fear of "poisoning" similar to the early fear of the chlorination of water supplies.

Our statesmanship here consists in convincing the skeptics that our epidemiological and laboratory studies are valid and that the benefits of fluoridation are not to be discarded lightly in the face of uninformed opposition. Convincing is an art, and it permits no arrogance or contempt of the opposition's point of view. In convincing, we must be completely candid and interpret the needs for more research in this field. One of the core facts of public health is the continuous search for techniques even more effective than those which we can endorse wholeheartedly at a given time. This is one of the most difficult facts to interpret to the average citizen and to appropriating bodies; yet this

task of interpretation is the very substance of our statesmanship.

Healthful Housing

There is one other environmental factor which as much as any other affects the solution of health problems as diverse as the control of heart disease, the promotion of mental health, and the prevention of acute infections. I refer to housing.

As Professor Winslow knows so well, as he has told us so many times, it is not enough that the American Public Health Association through his leadership has developed a remarkably accurate technique for evaluating the healthfulness of urban housing. Here is an instance in which the effectiveness of our techniques has exceeded the quality of our statesmanship.

Housing has been a major social problem of high priority throughout the world since before World War II. There has been tremendous enthusiasm and hope that housing and health agencies united could make substantial contributions to the solution of far-reaching problems affecting every family in the Nation. Yet few health departments have accepted their share of responsibility in working for more healthful housing.

At the present time, only 10 State health departments are actively assisting local health agencies in the development of housing programs. A few others have specific plans. Nearly 100 local health departments, however, have actively taken part in programs to improve housing conditions in the past few years. Only 13 States and 25 local health departments are conducting active programs in home accident prevention—closely related to housing. In States where progress has been made in either field, the responsibility for stimulating and assisting local activity has been delegated clearly to one staff member.

Statesmanship in the health aspects of housing calls for the active participation of local health agencies in community planning and the development of community housing programs. The fact that a city may have anywhere from 2 to 10 official agencies concerned with some phase of housing intensifies the challenge to be a public health statesman. The fact that some

States have official housing agencies invites State health authorities to step across the street and make known their interest and their willingness to cooperate in joint solutions of a major social problem.

Disease Control and Health Services

It is indeed a part of public health statesmanship to reach out in the community and identify those social and political forces that will make common cause with us for the solution of health problems whatever they may be. I warrant that many a public health worker in State and local agencies today would be agreeably surprised at the diversity and strength of the groups ready and eager for his leadership.

In this connection, we need to help our boards of health and county councils develop public health statesmanship attuned to society's current problems. Public health workers read, talk, and listen to seemingly endless conferences all emphasizing the shift in the age composition of the population, the increase in chronic diseases and impairments, the needs for community facilities and for the mobilization of community health resources. I regret to say that much of this healthy exchange of information is between those already converted to the cause; and in rare moments of discouragement I wonder how much of the discussion goes in one ear and out the other.

Chronic Disease and Disability

Chronic disease, chronic impairments, and the disabilities of old age are indeed the major health problems of America's aging population. Even with the widest possible latitude in interpreting the laws authorizing Federal grants-in-aid for general health services, maternal and child health, and services for crippled children, we cannot expect existing, and possibly shrinking, appropriations for these purposes to carry a forthright attack on chronic disease and the health problems of the aging. Here we must depend upon the special programs which have been made possible by the demands of society for action against the first causes of death and invalidism.

There is strong popular support for chronic

disease control and for health services to the aging. Yet I would be less than candid if I did not say that State and local health services in most of these fields are scanty and scattered. Lacks of sufficient funds, facilities, personnel, and effective medical techniques are commonly cited as causes of the lag in health department activity. Another deterrent frequently mentioned is the resistance of physicians to any public health activity in these areas. I am sure that this occurs because of failure to explain properly the programs to them.

The measure of our statesmanship, then, need not be in convincing society that chronic diseases and impairments are health problems of the first magnitude. Society has already given its mandate—and gives it year after year—in support of our programs and of the voluntary agencies devoted to these special problems. Rather the measure of our statesmanship will be in convincing the medical and community leaders, in convincing boards of health, county councils and other governing bodies, that these health problems are social and economic problems of the first magnitude and worthy of their full support and action.

Once the interrelationships of chronic disability, old age, and economic dependency are clearly understood, there is every reason to believe that general cooperation in the development of community programs, in which all physicians cooperate, for prevention, as well as for care of the chronically ill, will be forthcoming. The development of health services, especially preventive and restorative programs, aims to reduce dependency and the costs of public assistance and public medical care. The possibility of sound economy sharpens the humanitarian impulse for cooperation and adequate support.

If health officials continue to represent their needs and the community's needs as encompassing no more than the limited public health programs of prewar days, they cannot expect the medical profession, the boards, councils, mayors, governors, and legislatures to recognize the changing health needs or to select the issues which require priority in the formulation of public policy. Public health statesmanship, in many respects, consists in raising our sights, in applying our technical competence to health problems wherever they exist and are being neg-

lected. This implies, of course, that public health will also be self-critical, reviewing and appraising its own performance so that activities which no longer yield substantial benefits to the community will be modified or reduced in favor of more effort in neglected fields. It means also that public health must work more closely with the practicing physician and his organizations.

Promotion of Research

Scientific research has not yet given us the techniques we shall ultimately need for pinpointing the attack on chronic diseases or for developing a practical hygiene of the aging. At present, control of many chronic diseases is possible in the individual patient, but only through highly specialized skills and equipment. At present, medical rehabilitation of the disabled is possible in the individual patient, but only through specialized skills and equipment.

For these reasons, public health conducts and encourages a continuing search for simplified techniques which may be applied to the community as a whole or may be employed by the general practitioner in his office. For example, in cancer control we are searching for detection mechanisms that can be applied widely and inexpensively in effective case-finding programs. We are searching for cancerigenic agents in the environment, so that these hazards may be subjected to engineering, chemical, or other controls. In cancer, heart disease, arthritis and rheumatism, and many other serious ailments, we are supporting the unremitting search for therapies that ultimately may be placed in the hands of the general practitioner. Our goal in these present major diseases is not dissimilar to that which we have achieved in venereal disease control—with every private practitioner a "health officer," treating patients in his office; the health department maintaining supporting services of case finding, contact tracing, referral, and treatment of patients unable to pay for private care.

Obviously, we have not reached that point in the development of medical tools for such major problems as cancer and heart disease, comparable with serologic testing and penicillin therapy

in syphilis control. The nation-wide scientific effort in these fields and its accomplishments are another story, and one that is inspiring.

Society has made new demands on science since the war and has given science unprecedented financial support. We are all aware of how little money was available for medical research before the war. In less than a decade, the American people have reversed that condition in their determination to speed up the attainment of their health goals through expanded research. The essential leadership in the promotion of medical research has come direct from the public through their voluntary health organizations and their representatives in Congress.

The American Pattern

The development of the nation-wide effort in medical research thus has followed a characteristically American pattern: society leading, government aiding. Government aid to medical research has grown, but statesmanship from the outset has channeled the greatest part of that growth into the natural habitats of research—our universities, schools of medicine, and hospitals.

Cooperation of voluntary and governmental agencies with the universities and hospitals in medical research is a multimembered partnership. It has engendered mutual respect and greater skills in the solution of common problems. Science and society alike have benefited from this partnership in a vital area of research.

While new techniques for chronic disease control and hygiene of the aging remain in a twilight zone between experiment and universal use, it may be that this experienced partnership can speed the sound application of scientific advances. It may be that we need a "bridge" type of institution, with research, educational, and limited service functions, supported by many community, State, and national organizations.

New Partnerships

Certainly, in facing up to the specific problems of chronic disease and an aging population, it seems clear that public health needs to encourage and to develop many new types of partnership. One that seems of exceptional

value is partnership with university schools of medicine. The foresight of Professor Winslow in keeping postgraduate education in public health at Yale an integral part of the School of Medicine has yielded rich returns. The department's cooperation with the city of New Haven further illustrates the value of this partnership between the university and the community's health services.

Recently the University of Buffalo School of Medicine released the first annual report of its Chronic Disease Research Institute. This project is an interesting experiment in new partnerships. The Public Health Service made available its Buffalo hospital which we were closing and which could be easily converted into the type of facility envisaged by the group of community health statesmen. The New York State Health Department provided a grant-in-aid, and entered into active cooperation with the university. Support for various departments of the institute came from the National Foundation for Infantile Paralysis, the New York State Association for Crippled Children, the New York State Department of Mental Hygiene, the Western New York Heart Association, and the Arthritis and Rheumatism Foundation. The governing board is chaired by the dean of the School of Medicine, and includes representatives from local hospitals, the New York State Department of Health, and the Public Health Service. An able staff has done outstanding trail blazing in its first full year of teamwork.

Let me quote from the report:

"The future plans of the institute are inherent in its purpose: to do research in the field of chronic disease, to discover better and faster means of returning the chronically ill to maximal living within their individual limitations and to teach these newer, better techniques for handling the most complex problems in rehabilitation to medical personnel throughout the Niagara Frontier. The University of Buffalo Chronic Disease Research Institute is a small but complete institution actively serving medical science and education within the community."

Would that there were more such small, complete institutions serving such a purpose within more communities where the problems of the

chronically ill have previously been neglected. Perhaps this modest beginning will give us valuable clues to public health statesmanship in this area. In the meantime, health departments must press on toward society's health goals through the organization of community resources.

Community Health Organization

The ideal of community health organization is nothing less than the mobilization of all the rich and varied forces within an American community in free and friendly association to combat a common enemy and to strive for the common heritage of health and longevity. Inspired by some of our educational institutions, notably the Yale Department of Public Health, the Nation's official and voluntary health agencies have learned a good deal about community organization in the past 15 or 20 years. To their credit, they have put into practice a good deal of this knowledge. The translation of the ideal into practice, however, is difficult as is any activity depending primarily upon interpersonal and intergroup relationships.

In community organization as in program planning and administration, public health officials need especially to be alert in preserving flexibility. If we recall our criteria for statesmanship, we will see why this is so: "Wise statesmen foresee what time is bringing and try to shape institutions and mold men's thoughts and purposes in accordance with the change that is silently coming."

Community organization merely to preserve the status quo of public health can be as stultifying and as far from meeting the needs as can the administration of programs designed for the same purpose. Moreover, community organization of this sort fails to tap fully the creative energies of the community. In particular, the natural leaders outside of professional ranks or in professions not usually associated with public health may possess the humane impulses and the very creativity needed for developing new types of service essential in the solution of our major public health problems.

I know of such a leader who wants to construct a new type of institution for the care of certain types of cancer patients. It will be a modern apartment hotel specially designed and

furnished, constructed beside and with direct connections to a general hospital. The objective here is to provide efficiency apartments where family members or housekeepers may care for the patient in convalescent or other stages of his disease. Physicians would be at hand for routine supervision. When special therapeutic procedures must be carried out, the patient can be removed to the hospital immediately, and without loss of time and the added costs of an ambulance. More costly institutional facilities and services would be released for the care of more acutely ill patients.

This is a challenging idea, and one which may capture the interest of private enterprise, voluntary agencies, and religious organizations. It is an extension of the home care plan which has been developed so effectively by voluntary hospitals and agencies in a few parts of the country. We know that chronic disease and poverty go hand in hand, and that many times the home to which a patient would be returned cannot accommodate the needs of an invalid, no matter how willing the family may be to carry its share of the bedside care. Whether in a hospital-connected apartment hotel or at home, the costs of convalescent or terminal care of the chronically ill will be less than in a hospital. Hospital care for a patient costs three to five times more than care at home.

New and Effective Services

There are many other effective services that a community could provide for the chronically ill and the aging—services which not only relieve suffering and anxiety, but also bring about economics in the operation of public hospital and medical services. Some health departments around the country report housekeeping services, for example; but it is surprising how few communities have explored the possibilities. The New Haven Family Society, as I understand it, was one of the pioneering voluntary agencies to develop such a service.

The District of Columbia Health Department has developed a housekeeping service on a limited scale. Its primary purpose is to assist mothers in the postpartum period or in disabling illness. When these demands on its staff permit, however, the housekeeping service is available to aged persons.

Not long ago, an indomitable lady in her 80's suffered her fourth cerebral hemorrhage. The hospital insurance policy which she had carried for a number of years had been invalidated by previous hospitalization. Even had it been available, she did not want to go to the hospital because, she said, there was no one to look after her "boys"—an older brother and a mentally defective nephew of about 25 years. Here was a family that had never received a penny of public assistance; that owned its home; that managed to get along on the earned pensions of the two old people. The house-keeping service came to the rescue. And at least for 10 critical days when this family most needed help, there was someone to cook nourishing meals, do the laundry, keep the spotless home spotless, help the lady with her personal care, and, incidentally, save taxpayers the costs of hospitalizing her.

I have introduced this "human interest" story, because it exemplifies in many ways the human problems which make up the community problems, the public health problems; and it exemplifies the variety of human resources which must be called upon to help people meet their needs.

World Health

The mobilization of resources to meet human needs is the essence of world statesmanship today. It is in this international arena that public health workers meet face to face the inseparability of their sphere of activity from that of other specialists. Professor Winslow has been a world health statesman since the years of the League of Nations Health Section. He has been telling us all this while that public health does not and cannot function apart from the political, economic, educational, and cultural forces in whatever society it serves. Likewise, industry, commerce, agriculture, education, and government cannot function in isolation from public health.

Several hundred American public health workers are facing these interdependent problems today in their overseas assignments with the Mutual Security Agency and the Technical Cooperation Administration of the United States, and with the World Health Organiza-

tion and other international agencies. Their statesmanship will be measured not alone by their skill in applying modern techniques to the solution of age-old problems in entirely different social and physical settings. Public health statesmanship in the world community also consists in understanding the drive of poverty stricken peoples toward a better life, and in ability to work with representatives of other governments and of such related fields as agriculture, education, industrial production, transportation, and communication.

Public health workers have invaluable knowledge and experience to contribute to the planning and conduct of programs for social and economic improvement in underdeveloped areas. Failure to take into consideration the health and medical aspects of any large-scale economic project may well lead to failure of the total plan. Here again, as in other situations I have mentioned, public health workers, as statesmen, must be alert to the health components in diverse social problems; must challenge disregard of health; and must exercise the arts of interpretation and communication in order that their technical skills may be used constructively.

Conclusion

In this somewhat random discussion, I have left untouched many specific problems in public health which call for statesmanship and many fields in which statesmanship of a high order is being exercised. I shall leave it to you to fill the gaps, for the qualities that make up statesmanship in the boundless field of public health are the same in each sector. Let the measure of our statesmanship now and in the years to come be taken by this yardstick:

"The objective of public health is not merely the prolongation of life but the increase of vigor, efficiency, and happiness of all the members of our complex society. . . It is no easy task that we have set ourselves, no task for those who fear opposition or criticism. Vested interests related either to economic profit or to prestige may stoutly bar the path to achievement. Even

when these are not involved, we are confronted by the stubborn resistances of humanity to those new ideas and new forms of organization against which the average individual desperately defends himself. We must be wise and understanding as well as courageous. The tasks of the future cannot be solved by formulae alone; at point after point on the road there will be struggle in which wounds will be given and taken. Yet the objectives before us are so great that men of heart and courage will not hesitate to meet the risk. . . The road is long but the goal is worth the hazard. We need assume no unnecessary burdens nor needless quarrels. But when we are sure we are right, we must go ahead."

The time? 1936.

The place? The Milbank Memorial Fund Conference on Next Steps in Public Health (4).

The speaker? C.-E. A. Winslow—inspiration of this series of lectures—public health's great statesman.

International Certificate Requires Official Stamp

Health officers who do not have an official stamp to certify international vaccination certificates are requested to have a stamp made which includes the term "health officer" and the name and address of the health department. This stamp is required to attest to the signature of the immunizing physician, or physicians, affixed on the smallpox and cholera vaccination certificates entered in the new "International Certificates of Vaccination" form soon to be released. This document conforms with the International Sanitary Regulations effective October 1, 1952, and replaces the "International Certificate of Inoculation and Vaccination," PHS-731 (FQ), Rev. 12-48. No certificate is valid without the stamp of a "health officer." Public Health Service officers and medical officers of the Department of Defense will continue to use the seal of their respective service to authenticate these certificates.

Yellow fever vaccination certificates will be issued to the traveler at the time he receives his vaccination at one of the designated yellow fever vaccination centers. This certificate must carry the stamp of the designated clinic.

The Prevention of Rheumatic Fever

RHEUMATIC FEVER is a recurrent disease which can be prevented. It is now generally agreed that both the initial and recurrent attacks of the disease are usually precipitated by infections with beta hemolytic streptococci. Therefore, the prevention of rheumatic fever and rheumatic heart disease depends upon the control of streptococcal illnesses. This may be successfully accomplished by early and adequate treatment of streptococcal infections in all individuals and by prevention of streptococcal infections in rheumatic subjects.

Treatment of Streptococcal Infections

In the general population at least 3 percent of untreated streptococcal infections are followed by rheumatic fever. Among certain individuals, especially those with previous rheumatic fever, the incidence is much higher. Adequate and early penicillin treatment, however, will prevent most attacks of rheumatic fever and eliminate streptococci from the throat.

Diagnosis

In most instances it is possible to recognize streptococcal infections by their clinical manifestations but laboratory tests may assist in establishing the diagnosis.

Epidemiology

The seasonal pattern and presence of similar cases in the community or household may be helpful. For example, streptococcal infections

in the northern United States are most common from January through June. Likewise, a case of scarlet fever in one child would suggest that a sore throat in another has the same etiology.

Symptoms

Sore throat—onset sudden, in the tonsillar area, not in the trachea.

Headache—common.

Fever—variable, but generally from 101° to 104° F.

Abdominal pain—common, especially in children. Not too common in adults, but does occur.

Nausea and vomiting—common, especially in children.

These symptoms are usually *not* present: (1) simple coryza; (2) cough; (3) hoarseness.

Signs

Red throat—frequently beefy red, but if seen early the redness may be mild.

Exudate—usually present.

Glands—swollen, tender tonsillar glands at angle of jaw.

Rash—scarlatiniform (characteristic of scarlet fever, not common).

Discharge—otitis media and sinusitis indicated by (serous or purulent) aural or nasal

This statement was released for publication this month by the Council on Rheumatic Fever and Congenital Heart Disease of the American Heart Association. It was prepared by the council's committee on prevention of rheumatic fever of which Burtis B. Breese, M.D., is chairman and the following are members: Marjorie T. Bellows, Edward E. Fischel, M.D., Ann Kuttner, M.D., Benedict F. Massell, M.D., Charles H. Rammelkamp, Jr., M.D., and Edward R. Schlesinger, M.D.

discharge are frequent complications of streptococcal pharyngitis.

Laboratory

White blood count—generally over 12,000 and in children frequently over 20,000.

Throat culture—positive for hemolytic streptococci.

Therapeutic Response

Almost without exception patients with streptococcal infections are vastly improved within 24 hours after penicillin has been started and the temperature normal, or nearly so. This therapeutic response is characteristic and if it does not occur, the chances are much against the disease being due to hemolytic streptococci.

Treatment

In order to be effective, treatment should be started immediately when a streptococcal infection is suspected and continued for sufficient time to eradicate the streptococci from the throat.

Penicillin is the drug of choice for treating streptococcal infections.

Both the oral and the intramuscular routes of administration have been utilized successfully for penicillin therapy of streptococcal infections. Intramuscular injections have been proved to prevent rheumatic fever. The data on the value of oral penicillin as a preventive are less complete.

Oral administration in comparison to intramuscular administration has these advantages:

1. It is not as distasteful to many patients.
2. It requires fewer physician visits.

It has these disadvantages:

1. Larger amounts of penicillin must be used.
2. It is difficult to administer to vomiting or refractory children.
3. In some adults it gives rise to persistent diarrhea and pruritus ani.
4. It is difficult to be sure that treatment is continued for sufficient time and given in proper relation to meals to be effective.

RECOMMENDED SCHEDULES

Intramuscular Penicillin

Children—one intramuscular injection of 300,000 units of procaine penicillin with aluminum monostearate in oil *every third day for three doses.*

Adults—one intramuscular injection of 600,000 units procaine penicillin in aluminum monostearate *every third day for three doses.*

NOTE: Less preferable, but usually effective—two doses as above at 3-day intervals.

Oral Penicillin

First 5 days: 200,000 to 300,000 units $\frac{1}{2}$ to 1 hour before meals and at bedtime (total of 800,000 to 1.2 million units per day in four divided doses. Lesser amounts for children; larger amounts for adults).

Second 5 days: 200,000 to 250,000 units $\frac{1}{2}$ to 1 hour before meals (total 600,000 to 750,000 units per day in three divided doses).

NOTE: To be effective, therapy should be continued for the entire 10 days even though the temperature may return to normal and the patient may feel better within 1 or 2 days.

Combination of Intramuscular and Oral Penicillin

Therapy may begin with one injection of penicillin (300,000 units procaine penicillin with aluminum monostearate in oil) and then, beginning 3 days after the injection, continued for an additional 7 days with oral penicillin according to the schedule outlined above for the second 5 days.

Other Medication

Aureomycin: Less effective than penicillin in controlling streptococcal infection but it is especially useful in those sensitive to penicillin. Dosage: Total 10 mg. per pound of body weight in four divided doses daily for 2 days. Cut dose in half for remaining 8 days of therapy.

New preparations of penicillin: These may be effective and even preferable to the treatment schedules outlined, but at present they have not had sufficient trial to warrant their recommendation.

A Community Program for the Prevention Of Rheumatic Fever Recurrence

By MARY ALICE SMITH, M.D.

A PUBLIC HEALTH program to demonstrate techniques of community action in heart disease control began operation in Newton, Mass., in 1948. It was sponsored jointly by the Public Health Service of the Federal Security Agency, the Massachusetts Department of Public Health, and the Newton Health Department. The local medical profession was active in support of the project, and continuing leadership was given by a cardiac program committee composed of six physicians from the staff of the Newton-Wellesley Hospital. The progress of the Newton Heart Demonstration Program, as it was named, has been reported periodically (1-4). This paper is an interim accounting of rheumatic fever activities in the Newton demonstration.

Five general areas of activity were delineated at the beginning of the demonstration program in 1948: physician education, voluntary morbidity reporting, community organization, nutrition services, and rehabilitation. Subcommittees were organized for each of these areas. As experience was gained and the extent of the problem seen more clearly, some plans were modified. Morbidity reporting was abandoned, community organization was turned over to the Newton Community Council, and interest was directed to two or three new fields. One of

these, and a major heart disease problem in Newton, was rheumatic fever.

In 1949, the most recent year for which data are available, rheumatic fever and its sequelae were the leading causes of death from disease in the 10- to 14-year-old age group; in the group between 15 and 24 it was third, being exceeded only by tuberculosis and malignant neoplasms. The amount of chronic disability caused by rheumatic fever is also considerable. Recurrent attacks of rheumatic fever are common, particularly during the first few years following original onset, and each attack damages the heart more severely.

Rheumatic fever attacks are nearly always preceded by hemolytic streptococcal infections. The rheumatic child possesses a peculiar vulnerability and tissue reactivity to certain streptococcal infections (5). Most workers in the field now agree that the beta hemolytic streptococcus, Lancefield type A, precipitates the acute attack of rheumatic fever, even though the mechanism is as yet not fully understood (6). Children in families in which both parents have had rheumatic fever are much more likely to develop the disease than are children of parents with no such history. Due to the influences of the genetic factor and close association, siblings of rheumatic children are especially susceptible (5).

Early treatment of streptococcal infections with penicillin prevents rheumatic fever. In an Air Force study of some 2,300 persons, immediate and thorough treatment of streptococcal infections with penicillin effected a 91-percent reduction in the attack rate of rheumatic fever (7). The daily use of penicillin also has been

Dr. Smith, formerly medical officer-in-charge of the Newton (Mass.) Heart Demonstration Program, Division of Chronic Disease and Tuberculosis, Public Health Service, is now resident physician at Mount Auburn Hospital, Cambridge, Mass.

advocated to protect rheumatic fever patients against recurrent attacks. Other members of their families, too, should be treated when they have streptococcal sore throats. Massell and his colleagues at the House of the Good Samaritan in Boston developed drug schedules in 1948 for the protection of rheumatic fever patients against recurrences (8).

The Newton Program

On the basis of these and other clinical trials, the control of rheumatic fever in Newton seemed possible through application of existing knowledge even though it was incomplete. Previous reports have described in greater detail the following major steps in the development of the rheumatic fever control program in Newton, a Boston suburb with a population of 85,000:

1. At a meeting held in December 1949, the cardiac program committee authorized a telephone survey of physicians to determine the extent of preventive measures then being taken. From this survey, it was learned that virtually no efforts were being made to prevent recurrence of rheumatic fever.

2. As a result of these findings, a rheumatic fever subcommittee was set up to continue the program.

3. Massell's oral penicillin prophylactic schedules (4) were obtained by the subcommittee and introduced at one of the regular teaching sessions sponsored by the subcommittee on physician education.

4. A plan was adopted for penicillin to be dispensed by the health department upon the physician's prescription, at low cost, or free to those unable to pay.

5. So that physicians might acquaint rheumatic fever patients with the preventive care desirable for them, it was planned that the director of public health would write to rheumatic patients listed in his handicapped children's file, requesting them to visit their physicians for advice about prophylaxis.

6. In order to find families with children having a history of rheumatic fever, the cooperation of the public and parochial schools was obtained. A survey form distributed to 14,000 children requested their parents to indicate any

knowledge of rheumatic fever in the family and, for verification of diagnosis, to include the name of the family doctor.

7. It was also decided that a study of the prophylaxis program should be made to evaluate the effectiveness of efforts to place persons susceptible to rheumatic fever under their doctor's care, as well as the effectiveness of the penicillin dosage schedule itself in preventing recurrences of rheumatic fever.

During February and March 1950, these plans were put into effect: The availability of low-cost penicillin was announced; letters were sent to the parents of school children in an attempt to procure additional rheumatic fever histories; and families known to include rheumatic fever patients received letters asking them to visit their physicians for appropriate instruction. As new rheumatic fever families were found, they, too, were directed to their doctors for prophylactic care. During the early months of the program, also, personal visits were made to physicians known to have rheumatic fever patients in their practice. To determine the approximate prevalence of streptococcal infection in the community, free throat cultures of patients with suspected streptococcal infections were made by the Newton-Wellesley Hospital (9).

In the fall of 1950, another announcement was made concerning the availability of low-cost penicillin and use of the prophylactic schedules. As a diagnostic aid, the local physicians then received a copy of a definitive article by Dr. T. Duckett Jones, outlining criteria for the diagnosis of rheumatic fever (10).

The Study Group

In December 1949, just before the program was instituted, only 16 percent of the known rheumatic fever patients were receiving any kind of protection against recurrence of their rheumatic fever. After record searching, physician interviews and analysis of the family history questionnaires, it was believed that, as of January 18, 1952, all patients in need of prophylactic care were known to the health department. On that date there were 74 such patients in the community of whom 55 were known to have had their initial attack since the

A Community Program for the Prevention Of Rheumatic Fever Recurrence

By MARY ALICE SMITH, M.D.

A PUBLIC HEALTH program to demonstrate techniques of community action in heart disease control began operation in Newton, Mass., in 1948. It was sponsored jointly by the Public Health Service of the Federal Security Agency, the Massachusetts Department of Public Health, and the Newton Health Department. The local medical profession was active in support of the project, and continuing leadership was given by a cardiac program committee composed of six physicians from the staff of the Newton-Wellesley Hospital. The progress of the Newton Heart Demonstration Program, as it was named, has been reported periodically (1-4). This paper is an interim accounting of rheumatic fever activities in the Newton demonstration.

Five general areas of activity were delineated at the beginning of the demonstration program in 1948: physician education, voluntary morbidity reporting, community organization, nutrition services, and rehabilitation. Subcommittees were organized for each of these areas. As experience was gained and the extent of the problem seen more clearly, some plans were modified. Morbidity reporting was abandoned, community organization was turned over to the Newton Community Council, and interest was directed to two or three new fields. One of

these, and a major heart disease problem in Newton, was rheumatic fever.

In 1949, the most recent year for which data are available, rheumatic fever and its sequelae were the leading causes of death from disease in the 10- to 14-year-old age group; in the group between 15 and 24 it was third, being exceeded only by tuberculosis and malignant neoplasms. The amount of chronic disability caused by rheumatic fever is also considerable. Recurrent attacks of rheumatic fever are common, particularly during the first few years following original onset, and each attack damages the heart more severely.

Rheumatic fever attacks are nearly always preceded by hemolytic streptococcal infections. The rheumatic child possesses a peculiar vulnerability and tissue reactivity to certain streptococcal infections (5). Most workers in the field now agree that the beta hemolytic streptococcus, Lancefield type A, precipitates the acute attack of rheumatic fever, even though the mechanism is as yet not fully understood (6). Children in families in which both parents have had rheumatic fever are much more likely to develop the disease than are children of parents with no such history. Due to the influences of the genetic factor and close association, siblings of rheumatic children are especially susceptible (5).

Early treatment of streptococcal infections with penicillin prevents rheumatic fever. In an Air Force study of some 2,300 persons, immediate and thorough treatment of streptococcal infections with penicillin effected a 91-percent reduction in the attack rate of rheumatic fever (7). The daily use of penicillin also has been

Dr. Smith, formerly medical officer-in-charge of the Newton (Mass.) Heart Demonstration Program, Division of Chronic Disease and Tuberculosis, Public Health Service, is now resident physician at Mount Auburn Hospital, Cambridge, Mass.

of 1950, coincident with the major education effort. The remaining 11 were added to the series at a rate of about 1 each month thereafter.

Interviews with the physicians brought out the fact that, in more than half the instances where patients were replenishing supplies only irregularly, the physicians had been unaware of the irregularities until these were brought to their attention. The same physicians were asked for their reaction to the suggestion that the health department should send out reminder cards to patients when their supply should have been consumed. Only about half the opinions favored this measure, and the suggestion was not pursued.

Some physicians were able to keep all their patients in the "regular" penicillin category throughout the period of this study. Others were unsuccessful in teaching all of their patients the advantages of the regular use of penicillin.

Three physicians had patients in all three of the treatment categories—prophylactic penicillin, sulfonamides, immediate treatment for streptococcal infections.

Of the 28 patients in the "regular" penicillin group, their physicians reported that only one had had a streptococcal infection while receiving penicillin—a patient with scarlet fever in whom repeated throat cultures revealed no beta hemolytic streptococci. At least 11 other non-streptococcal infections, however, did occur within this same group. No penicillin reactions were reported by physicians.

There were no recurrences of rheumatic fever among the 74 patients through January 18, 1952.

The program will be continued by a routine procedure in which, on finding children with rheumatic fever (as, for example, through a school physical examination), the health de-

partment will send the child's physician an announcement of the availability of penicillin and a request that he return a card noting prophylactic measures being taken and permissible physical education activities at school.

Employment of the Older Worker

By THEODORE G. KLUMPP, M.D.

THE PRACTICE of compulsory retirement on pension at a fixed chronological age is a fairly new practice. Its adoption started with the incredibly swift industrialization of the 1900's and the growth of large business units.

The acceptance of pension retirement plans by industry was hailed on all sides as a great advance. Previously, older workers had simply been discharged without provision for their future welfare. The conventional idea had prevailed that workers should save for their old age or become dependent on adult offspring or on charity. Industry's voluntary acknowledgment of a concern for the welfare of its workers beyond their years of service was indeed a step forward.

Now, industry has accustomed itself to the practice of compulsory pensioned retirement at a fixed calendar age. The practice is simple in administration, and, during slack periods especially, it provides an easy, automatic way of casting off a number of surplus workers who are generally on top of the pay scale. In addition, compulsory retirement opens doors for advancement, a custom which business will not easily yield.

Human Side of Compulsory Retirement

There is growing recognition, however, that the mere provision of bread and shelter for older persons is not enough. No longer are they regarded as a statistical group—a series of figures on a sheet of paper—but they are regarded as individuals whose happiness is of increasing concern.

Dr. Klumpp is president of Winthrop-Stearns, Inc., New York City.

"Employment, . . . 'nature's physician,' is so essential to human happiness that indolence is justly considered the mother of misery," wrote Robert Burton over three centuries ago (1).

Youth can be content with opiate dreams of future achievements. But those approaching 50 or 60 can no longer derive solace from dreams of the future. Age plays for real stakes. It wants something to do, and that something must be real. Useful work is the most real thing we have to sustain us in this life of ours.

Compulsory retirement at a fixed calendar age treats all workers alike. But all workers are not alike. Some have the intellectual resources to occupy themselves without an occupation. Most people, however, are not happy when they are idle. In the words of the physiologist, Dr. A. J. Carlson, "The physiologic age of the worker is not synonymous with his chronologic age, owing to the individual variables in heredity, mode of living, accidents, and sequelae of diseases" (2).

What is popularly called old age is in truth only that period of life during which the rate of decline of cells, tissues, or organs has progressed to the point where the decline is visible to the naked eye. The decline begins at conception, and it is not the same for all human beings nor is it equivalent for all organs and functions of the body. This is well illustrated by the life of Christen Jacobsen Dragenberg, the Dane who died in 1772 at the age of 146. At 13, he went to sea. He took part in the service of three kings warring against Sweden and served many nations in merchant navies. When nearly 70, he was taken prisoner by Algerian pirates and sold as a slave. After 15 years, he escaped and again went to war against Sweden. At 111, he married a 60-year-old woman.

He outlived her and, when he was 130, proposed to several women. He was rejected but mastered his disappointment and lived on for 16 years (3).

Our society has been quite illogical and inconsistent in its attitude toward the older worker.

On the one hand, we have not objected to electing or appointing older persons to positions of greatest responsibility. In the 81st Congress (1st and 2d Sessions, 1949-50), 34 percent of the Senators were over 60, as were almost 19 percent of the Representatives. In a study made in 1946 I found that over 44 percent of 500 top business executives who were listed consecutively in the 1946 edition of "Poor's Register" were over 60. Bernard Barnet, 82 years of age; Arturo Toscanini, 85; Herbert Hoover, 78; General George Marshall, 71; and Ambassador Walter Gifford, 67, have not found their age an obstacle in the path of progress.

On the other hand, we maintain blind and unselective compulsory retirement rules for the rank and file of workers. Such rules automatically eliminate those who have reached the same age regardless of their fitness, ability, and contribution to the group.

Economic Side of Compulsory Retirement

From an economic point of view, it would be sound policy to permit older people to work as long as they are productive and desire to work. Since a country's national wealth, purchasing power, and standard of living rest squarely on productivity, our economic stream flows best when we have the largest number of active producer-consumers. The unemployed contribute nothing to the economy.

In about 30 years, the United States will have more individuals over 45 years of age than the 61 million (4) gainfully employed today. It is conservatively estimated that by 1980 there will be between 160 and 180 million people; 66 million of them will be 45 and over; 24 million will be 65 and over.

If in 1980, for example, we were to employ only one-fifth of the estimated 24 million people over 65, at an average annual salary of \$2,500, they would earn for themselves 12 billion dollars each year. This load of support would be

taken largely off the shoulders of young workers. The more emeritus workers, the greater the burdens will be on those active workers who must support them, either by direct contribution or by taxes, along with their own families.

The argument has been made that older workers should be cleared out to make way for younger ones. This is only another way of saying that there are more workers than jobs. During World War II, no one was afraid that the old or the physically handicapped were taking jobs from younger, more able people. There is no arbitrary age at which the older worker begins to repress the younger. Every older individual high on the ladder of advancement holds a job a younger person feels he can fill. This will be just as true in 1980, when we may be forced to retire people at 45 or 50, if we have failed to find a more logical way of reducing the disparity between jobs and workers.

From another point of view—we are witnessing today a great ground swell of public sentiment in favor of State or Federal old age pensions for those over 65. The figure of \$100 a month is one prominently mentioned objective. By 1980, this could cost the country \$28,800,000,000. When this sum is added to other welfare benefits which have been adopted, or probably will be, we are confronted with an astronomical figure which some statesmen declare we cannot afford.

Why Selective Retirement?

In view of these facts, it is increasingly clear we must overcome the prejudices of present-day employers against hiring older workers and retention of the fit. The fixed formula of retirement must be made more flexible and must be broken down into alternative possibilities:

Continued work for the fully productive.

Job reassignments for those capable of performing other duties.

Down-grading and "tapering off" when necessary or desirable.

A whole new system of fitness testing, job analysis, and selective placement awaits development.

To encourage the cooperation of industry, some economists have suggested a pension tax rebate so that employers will keep workers be-

yond the compulsory retirement age. Henry W. Steinhaus, in a study for the National Industrial Conference Board, considers that an employers' tax incentive is feasible, and, in addition, he proposes an increase in pension benefits for employees for each year their retirement is deferred beyond age 65 (5).

We choose and we select when we hire. Can't we do the same when we retire our workers?

We should devise methods of determining which people are capable at 65 or 70 and which people are not. A man isn't fit one day and unfit the next because a page of the calendar has turned. By the same token, he isn't conservative one day and liberal the next, or cautious one day and reckless the next.

The Armed Forces have successfully handled the problem of selective retirement by retirement board procedures which determine the physical and mental fitness of servicemen and officers in the light of the current needs of the services. Perhaps industry could find in these procedures a sound basic pattern which can be adapted to its own purpose. An infinitesimally small number of industrial organizations have practiced selective retirement with success.

In any circumstances, a social rule which eliminates the fit with the unfit, which destroys the good with the bad, or which punishes the innocent with the wicked is not a good rule. Social progress may be measured, in the last analysis, by the degree of skill and discrimination with which society solves the individual problems of its members.

Bernard Baruch is quoted in the *Washington Daily News* of December 29, 1949, as saying:

"How hideous a mockery it would be if, as a result of advances in medicine, surgery, hygiene, and higher living standards, older people were left willing and able to work but Society deprived them of something to do."

Fortunately, the idea that compulsory retirement on a calendar age basis is wrong is gaining general acceptance. The National Health Assembly on May 4, 1948, unanimously adopted a recommendation to this effect (6).

In his 1948 report to the President on the Nation's health, the Federal Security Administrator states:

"Efforts should be directed toward accomplishing selective retirement based on individual capacity rather than age . . . Both public and private employers would profit equally with employees from working out techniques for gradually relieving individuals of more taxing responsibilities as they develop the limitations of advancing age, by keeping pay commensurate with productivity and by full use of the possibilities of vocational retraining" (7).

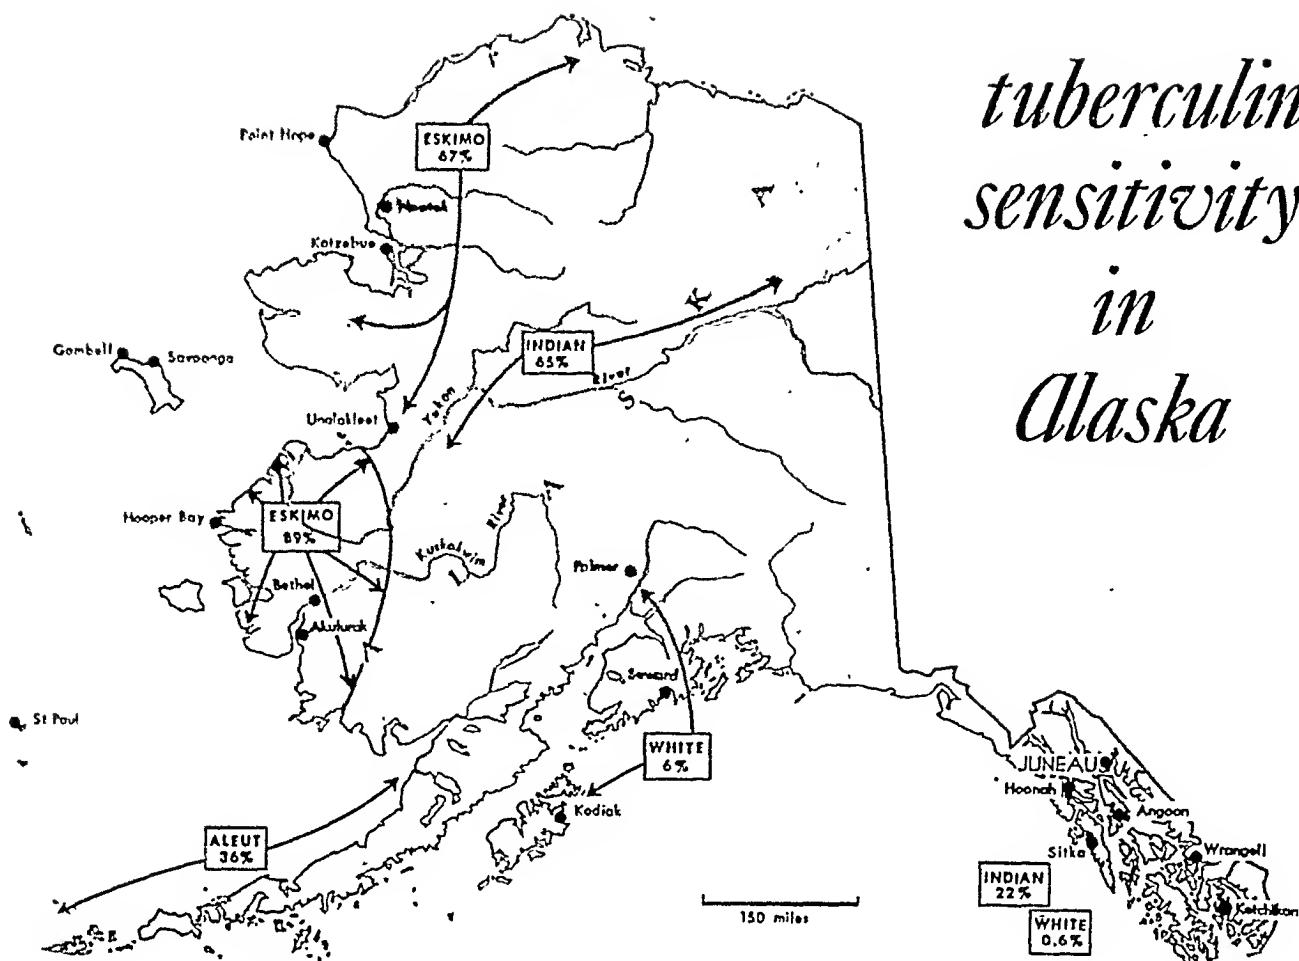

But ideas are sterile unless we act on them.

tuberculin sensitivity in Alaska

Towns and villages shown are those where 100 or more tests are counted.
Percentages are reactor rates among 5- and 8-year-old children.

By EDWARD S. WEISS, M.P.H.

ALTHOUGH it is generally recognized that tuberculosis constitutes one of the most serious health problems in Alaska, few specific data are available for measuring its extent. The commissioner of health for Alaska has quoted a 1950 tuberculosis death rate among the Eskimos, Indians, and Aleuts of 600 per 100,000 population and a prevalence of active tuberculosis of 25 percent in some villages (1). In comparison, the estimated tuberculosis death

rate in the continental United States in 1950 was about 23 per 100,000 population (2).

Prerequisite to a reasonable interpretation of these figures for Alaska, however, is some knowledge of the number and distribution of the people. The 1950 civilian population, based on Bureau of the Census figures (3) was about 108,000: Eskimos, Indians, and Aleuts numbered 34,000; other civilians, mostly whites, 74,000. The white population is concentrated in a few comparatively large cities, but the Eskimo, Indian, and Aleut population is scattered throughout the Territory in many small villages (figs. 1 and 2). Evaluation of the magnitude of the tuberculosis problem

Mr. Weiss is chief of the epidemiology and biometry branch, Arctic Health Research Center, Public Health Service, Anchorage, Alaska.

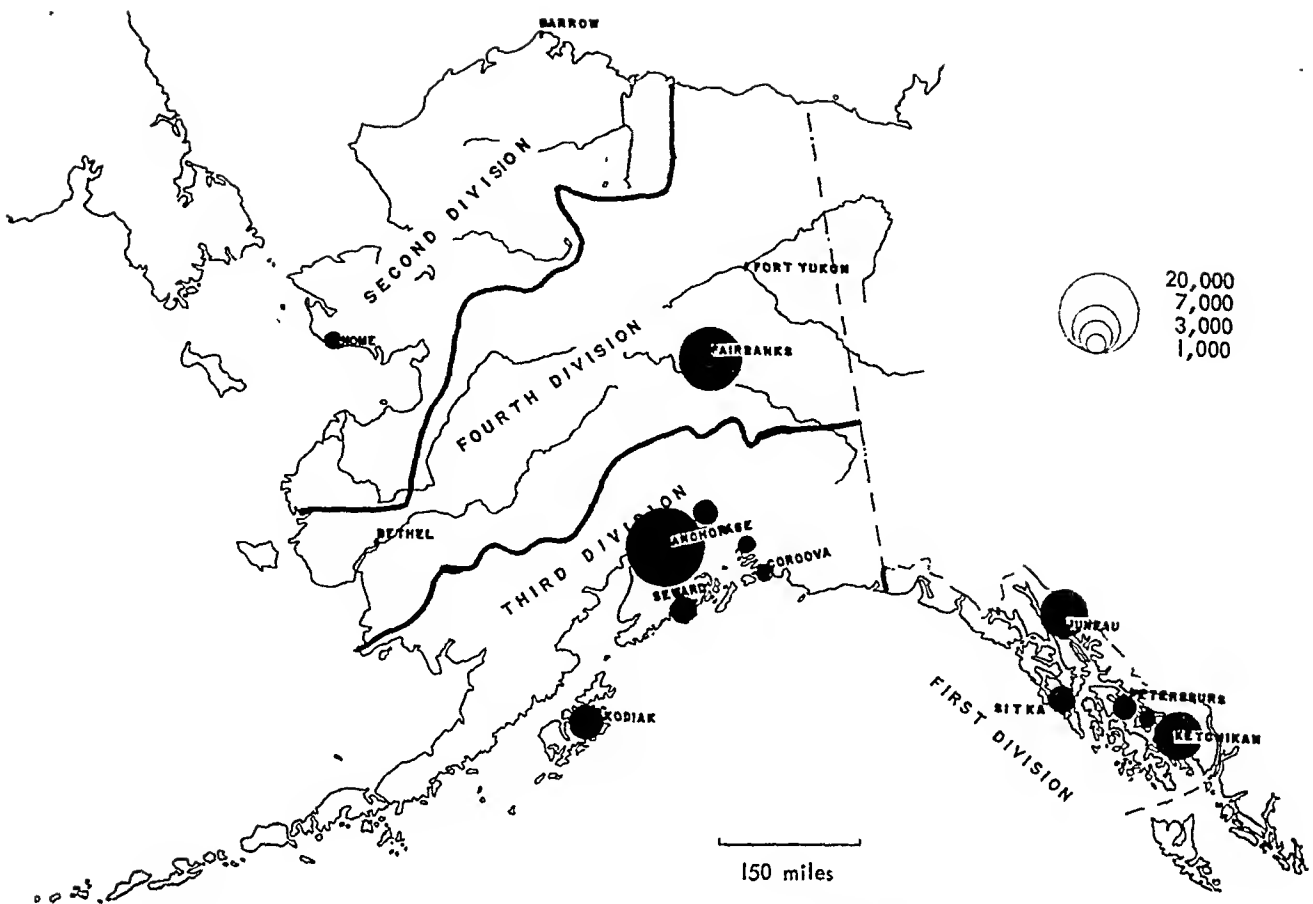

Figure 1. Estimated distribution of the white population of Alaska, 1950.

therefore presents difficulties not usually encountered in public health practice in the States.

The 90-percent increase in the white civilian population of Alaska between 1939 and 1950 was largely due to the entry of employable adults and their children into the Anchorage and Fairbanks areas. Since many of these newer residents, as well as some of the older ones, return to the States for medical care, especially when extended hospitalization is involved, tuberculosis mortality statistics are of little value with respect to this group.

Rejecting mortality statistics as an index of prevalence leaves two practical measures: mass X-ray survey results and tuberculin sensitivity data. Although records of both are available, the latter provide greater coverage numerically and geographically. They are a byproduct of an extensive BCG program of the Alaska Department of Health. Since age-specific tuberculin sensitivity rates are among the most useful measures of the prevalence of infection, the results of tuberculin tests have been tabulated

and analyzed for specific racial groups in designated geographical areas in order to achieve a preliminary definition of the tuberculosis problem.

Materials and Methods

In September 1948, the Alaska Department of Health began its BCG program. By the spring of 1951, when the program was interrupted for administrative reasons, about 30,000 tuberculin tests had been performed on civilian persons of all ages throughout the Territory.

In general, groups which were predominantly Eskimo, Indian, or Aleut were tested with a dose of 0.00002 mg. (1 tuberculin unit) of PPD-S; those which were predominantly white, with 0.0002 mg. (10 tuberculin units) of the same product. However, the Aleuts whose records were selected for this study received a dose of 0.0002 mg. of the tuberculin.

Results of the tests were recorded only as negative or positive. The reaction was classi-

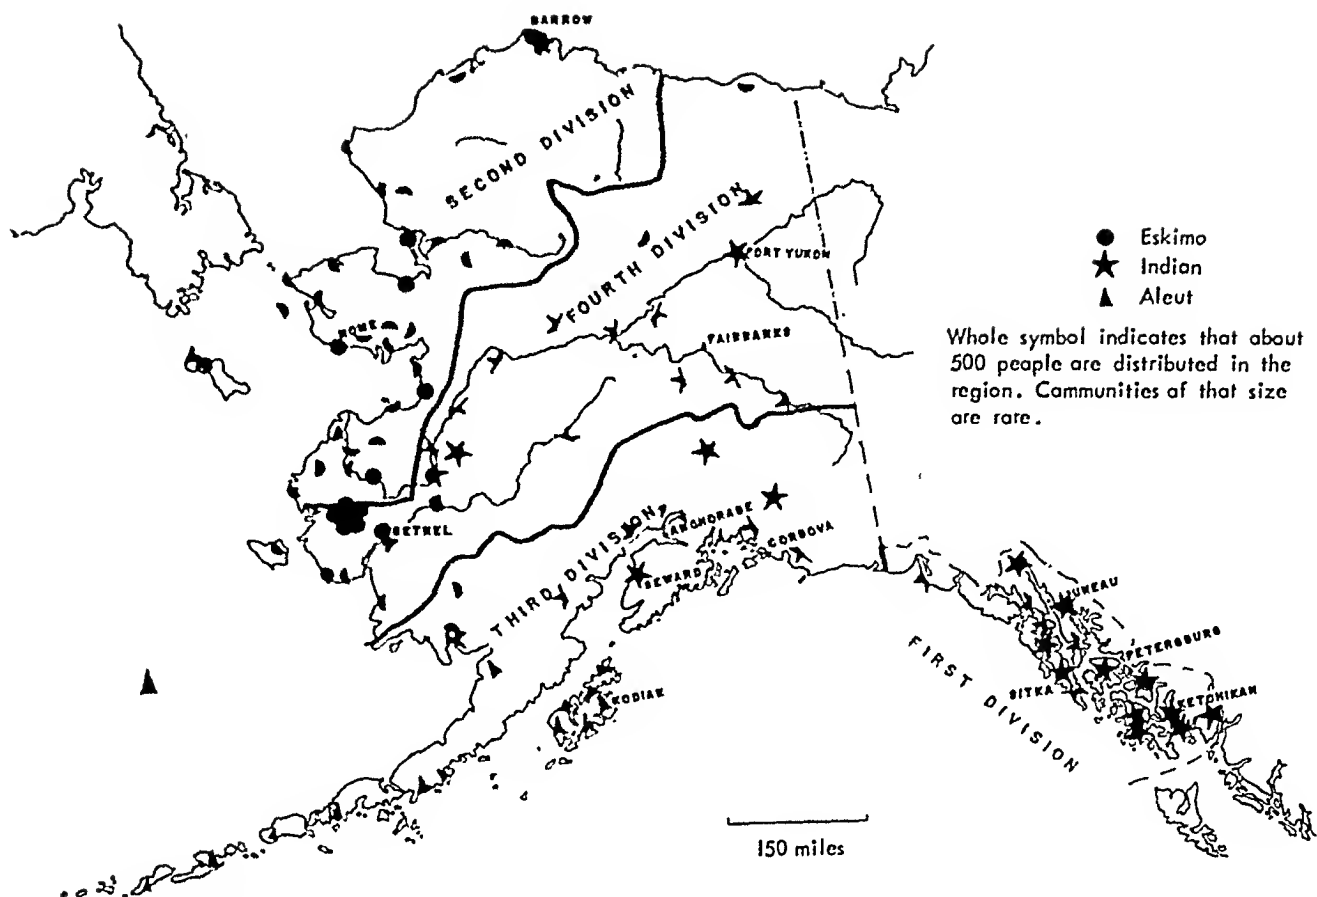

Figure 2. Estimated distribution of Eskimo, Indian, and Aleut population of Alaska, 1950.

fied positive if the area of induration measured 8 mm. or more in diameter 48 hours after injection of the tuberculin.

The records of 6,504 children through age 14 years who were tested on the first visit of the BCG team to their respective communities were selected for tabulation and analysis. The age limit of 14 years was set when preliminary examination of the data disclosed that almost all native adults and older children were reactors. Over half of the original group of records was eliminated on this basis. The availability of two sets of data based on different tuberculin doses and the existence of less than 20 records for small isolated communities were other reasons for eliminating records.

Although combination of tests with different doses was avoided, no further distinction was made between the results of tests with the 0.0002 mg. and the 0.00002 mg. doses. Furelow and his colleagues (4) showed that although there was a marked increase in the number of reactors among tuberculous children as the PPD dose

was increased from 0.000001 mg. (0.05 tuberculin unit) to 0.00001 mg. (0.5 tuberculin unit), the latter dose brought the S-shaped dose-response curve so near its upper asymptote that the next increase to 0.0001 mg. (5 tuberculin units) elicited few additional reactors. They further showed that the greatest increments in reactors among apparently nontuberculous children were in the tenfold steps above 0.0001 mg.

The difference in the two doses used in the Alaskan program, therefore, cannot account for more than a negligible portion of the differences in sensitivity rates.

Results

The age-specific tuberculin sensitivity rates for each of seven groups, homogeneous with respect to race, area, dose, and pattern of response, and the observations from which they were computed are presented in the table.

A number of alternative ways of summarizing these data for comparative purposes are

Tuberculin sensitivity, by age, race, and area, Alaska, 1948-51

Age (in years)	Eskimo		Indian		Aleut	White

13 to 14-----	151	160	14	71	62	158	105

available. For example, the annual infection rate required to establish the observed levels of sensitivity or the age at which 50 percent of the children had attained sensitivity to the antigen might be used. In preference to these more elegant parameters, a simple expression of the proportion of reactors in the middle age groups, 5 through 8 years old, was selected.

The proportions of reactors among children 5 to 8 years old in each of the seven groups, designated by race and area, are shown on the map on the title page. They range from an almost unbelievable high of 89 percent for Eskimos in the region of the Yukon and Kuskokwim Deltas to 0.6 percent for white children in the southeastern panhandle.

The Eskimo children of the northwest apparently are less exposed to infection than their southern kinsmen, for the sensitivity rate there is 67 percent, about the same as that found among the Indians of the interior (65 percent). Southeastern Indians appear to be in a compar-

atively favorable condition, with 22 percent of their 5- to 8-year-old children reacting to tuberculin.

The comparable rate among Aleuts is 36 percent, very high in comparison to the 6 percent and 0.6 percent observed among white children in the two designated areas but much lower than that for either group of Eskimos or the Indians of the interior.

Discussion

The variations in sensitivity among the seven specified Alaskan groups almost cover the range recorded for the rest of the world. No available report, not even that based on tests of "Chinese children of the poorest classes" (5), shows levels of sensitivity exceeding those observed among the delta Eskimos. On the other hand, few communities in the United States show levels lower than those recorded for the white children of the panhandle. Myers, for example,

states that there are now many schools in Minnesota in which no child reacts to tuberculin (6). That goal is within the grasp of one group of Alaskans, but at present completely out of the reach of many others.

The success of any control program attempting to deal with tuberculosis in Alaska or even with tuberculosis among the Eskimo, Indian, and Aleut population in Alaska will require an appropriate "area control" viewpoint. Different plans, procedures, and objectives may have to be used for various areas.

Summary and Conclusion

1. The records of tuberculin tests on 2,762 Eskimos, 903 Indians, 582 Aleuts, and 2,257 white children through age 14 years were selected from records of the Alaska BCG program.

2. The records were tabulated to show the age-specific sensitivity rates prevailing in selected population groups.

3. The rates observed for Eskimo, Indian, and Aleut children 5 to 8 years old ranged from 89 percent among a large group of Eskimos to 22 percent among Indians of the southeastern panhandle. The rate for another group of Eskimos and the Indians of the interior was approximately 65 percent.

4. Sensitivity rates of 0.6 and 6.0 (similar to those observed in cities of the United States)

were found among white children aged 5 to 8 years old.

Although conventional control measures are probably adequate for maintaining or reducing the low prevalence of tuberculosis among the white residents of the Territory and the Indians of the southeastern area, it is unlikely that they can succeed among the other groups in Alaska.

Complement Fixation Tests For Murine Typhus On Small Mammals

By RUTH KEATON, B.S.

BILLIE JO NASH, B.A.

J. N. MURPHY, JR., M.A., M.S.P.H.

J. V. IRONS, Sc.D.

THE IMPORTANCE of commensal rats and their fleas in the epidemiology of endemic typhus was well established in 1931 (1,2). Following Dyer's report (3) on the experimental infection of the woodchuck, meadow mouse, and whitefooted mouse with endemic typhus, Brigham (4, 5) indicated that many species of rodents and other mammals were apparently susceptible to endemic typhus. Sparrow (6) recovered a strain of endemic typhus rickettsiae in the house mouse (*Mus musculus*), as did Brigham (7) with his experiments on a field mouse (*Peromyscus* sp.).

In view of the wide distribution of endemic typhus in commensal rats in Lavaca County reported by Irons and associates (8), inquiry into the possible occurrence of infection in other small mammals seemed worth while. Morlan and co-workers (9) used the complement fixation test as an indication of natural infection, but Rickard and Worth (10) considered the findings on the wild-caught cotton rat (*Sigmodon hispidus*) to be nonspecific.

Methods

Live animals were captured in 1945 and 1946 near Hallettsville, in southeast Texas. Generally, the ectoparasites were identified while alive. The ectoparasites to be tested for typhus were appropriately pooled and stored on dry

ice under glass seal. The animals' brains were removed for tissue infectivity tests and were also stored on dry ice. Tests of the tissues of serologically reactive animals and pools of their fleas aided in evaluating the significance of low titers.

Blood samples were obtained by cardiac puncture soon after capture of the animals. Serums were separated aseptically and were kept at ice-box temperature until examination. Serums were inactivated 30 minutes immediately before testing at 56° C. Each serum was subjected to a quantitative complement fixation test employing endemic typhus rickettsiae. A slight modification of the procedure described by Brigham and Bengtson (11) was used. The result was recorded as reactive when a 3+ or greater reaction was obtained with satisfactory controls at a 1:20 or greater dilution of serum.

When a serum was reactive, the corresponding brain suspension was emulsified and inoculated individually into hamsters for evidence of typhus. With negative serologic findings, the brains of animals of the same species, particularly from the same trapping area, were similarly tested in pools of varying number. Pools of fleas from the same host species taken in the same area were similarly tested. Each hamster was bled twice, both before inoculation and 3 or 4 weeks later, and the serums were run in the quantitative complement fixation test. With positive findings, titers tended to be high on the second bleeding. This was the procedure recommended by Plotz, Wertman, and Bennett (12) for identifying rickettsial agents isolated in guinea pigs or mice. The utilization of specific complement fixation tests is much more economical than cross immunity and other tests in the guinea pig for identifying endemic typhus rickettsiae. A summary of findings is shown in the table.

The brain tissues of 3 of 17 house mice (*Mus musculus*) taken from 3 of 44 places surveyed yielded typhus rickettsiae. Most of the house mice were trapped on premises in close association with commensal rats. Curiously enough, those trapped in the fields were uniformly negative. Native rats and mice were found strictly in the fields. Tests of the brain tissues from the cotton rat (*Sigmodon hispidus*), the pack rat

Miss Keaton and Miss Nash are bacteriologists; Mr. Murphy is associate director, and Dr. Irons is director of the bureau of laboratories, Texas State Department of Health.

<i>Reithrodontomys fulvescens</i> (harvest mouse).....	9	0	-----	-----	-----

(*Neotoma floridana*), and the opossum (*Didelphis virginiana*) were uniformly negative.

A pool of 20 fleas (*Ctenocephalides felis*), collected from two opossums at Hallettsville in the summer of 1946 and not previously reported, gave an unequivocal positive test for typhus. These opossums were trapped in an oil mill which had not been dusted with DDT. The opossums showed negative complement fixation tests. Eight pools of fleas collected from negative rats and mice and tested for harborage of typhus rickettsiae gave negative results.

Discussion

Although occasional serums from cotton rats, wood rats, and from an opossum were reactive in the complement fixation test for endemic typhus, the titers were relatively low. However, similar findings on commensal rats probably would have been considered as evidence of infection or immunity to typhus. Low titers and failure to demonstrate the infectivity of brain tissues of cotton rats, pack rats, or opossums cast doubt on the specificity of serologic findings on these animals. The percentage of house mice showing positive serologic findings was also relatively low, but the titers were not invariably low, and endemic typhus rickettsiae were obtained from the brains of three house mice. The relatively few places harboring house mice with evidence of past infection contrasted sharply with findings for the domestic rat (8).

The finding of typhus rickettsiae in a pool of fleas collected from the two opossums, and in

other pools of fleas collected from nonmurine hosts (13, 14) was perhaps fortuitous, as it is possible that the fleas had acquired the infection from rats. At any rate, these findings do not in any way detract from the primary role of commensal rats in the epidemiology of endemic typhus fever.

Summary

Endemic typhus rickettsiae were recovered from brains of three house mice taken from human habitations and from a pool of 20 fleas collected from two opossums.

House mice trapped in fields were uniformly negative.

Unequivocal evidence of typhus in small mammals other than commensal rats and mice was not obtained.

Serologic findings on the pack rat, cotton rat, and opossum were of doubtful significance.

ACKNOWLEDGMENT

The Lederle Laboratories, Pearl River, N. Y., supplied the endemic typhus antigen used in the study.

given State may vary markedly from the provisions applicable to counties and districts. It is also apparent that certain types of local governmental units are frequently exempt from general statutory provisions, but are covered by special statutes not generally applicable to all local governmental units.

The existence of specific statutes dealing with various classes of local governmental areas does much to complicate the establishment of local health departments. For example, in one State there are six classes of local governmental areas which may form a local health department, provision being made for each class under a different set of statutes. New legislation introduced under these circumstances frequently only adds another procedure by which local health departments may be formed, rather than clarifying and simplifying the several existing provisions for the formation of local health departments.

Local Boards of Health

Local boards of health are mandatory by statute in at least some type of local governmental area in 41 States. Six other States have permissive provisions for boards of health applicable to some local governmental areas. There is only one State in which no statutory provision, either mandatory or permissive, is made for boards of health. Regulations for the establishment of local boards of health exist in only two States, and in both of these States statutory requirements also are present. Although provided for by law, local boards of health do not actually function in some States.

Table 1 indicates that in 24 States, boards of health are provided for by mandatory statutes generally applicable only to local areas. Three States have mandatory provisions applicable only to cities. Four States have permissive authority which is generally applicable to local areas, and 2 States have such provisions applicable only to cities. There are 14 States in which it is mandatory for some governmental areas to have boards of health while it is permissive for other areas to have them. There are 3 States in which current statutes require local areas to have boards of health, but legislation recently enacted makes it permissive for

¹ Since the basic governmental unit in New England is the town, the data for these States have been included in the same category as county data for the other States.

² Figures in parentheses indicate the number of States included in the tabulation in which the provision is applicable only to certain local governmental areas or only under certain conditions.

newly created health departments to have such boards.

State health officers, when asked to comment on the advisability of local boards of health, almost unanimously expressed the opinion that such a body should exist, but expressions as to its function varied widely. Three State health officers questioned the desirability of a local board, 7 felt it should function as an advisory body only, while 33 felt that it should serve as a policy-making body through the adoption of rules and regulations.

District Boards of Health

Districts may be defined as a health jurisdiction which encompasses more than a single local governmental area. Such districts may be city-county, multicounty, multicity, or any other combination of local governmental areas. Thirty-six States provide through statute for some type of board of health in districts and one State does so by generally accepted practice.

There are three general types of boards of health established in areas comprising health districts: (a) A district board of health repre-

senting all constituent areas within the district; (b) both a district board of health and separate boards for each constituent area; and (c) a separate board of health for each constituent governmental area within the district (table 2).

Twenty-nine States provide for the first type by statute. Five States have statutory provisions for district boards of health which provide that the district board be composed of members of the several separate boards of health of the individual governmental areas of the district. Under such a plan, each constituent area has a separate board of health and also has representation on the district board. Two States provide by statute for a separate board for each constituent area, and one State does so by commonly accepted practice.

Appointment of Boards

Statutes sometimes name certain local legislative or administrative officials who shall constitute the board of health, or in other instances the responsibility for the appointment of the board may be delegated by law to either the local legislative body or some administrative official. The State health officer or the State board of health appoints local boards of health in a few States. Representatives on district boards of health are generally appointed either by the local legislative body or an administrative official of each constituent governmental unit in the district. Sometimes members of

the legislative body or an administrative official of each constituent area serve on the district board.

Almost universally State health officers in commenting on the method of appointing local boards of health indicated that members of such boards should be appointed by the local legislative body or by an administrative officer. A few State health officers pointed out that a primary consideration was that appointments be nonpolitical in nature. The statutes of some States specifically limit the number of board members that may be from the same political party.

Local Board Representation

Table 3 indicates that 34 States have statutes which provide for professional representation on boards of health, but in 15 of these States such provisions are limited to certain areas or conditions in their application. Two States provide for professional representation by commonly accepted practice under certain conditions. Professional representation usually consists of one or more doctors of medicine, but in a limited number of States dentists and pharmacists are also included. By prescribing that certain officials constitute the board of health, some States practically preclude professional representation on such boards. Most State health officers felt that the medical profession should be represented on boards of health, but one-third of them indicated that physicians should not constitute a majority of the membership.

Nearly three-fourths of the States provide that certain local administrative officials shall be members of the board of health by reason of some other county or city office which they hold. In 14 States such provisions are applicable only to certain areas or are qualified as to the conditions under which they are applicable. Frequently, separate statutory provisions applicable to cities or to districts exist in addition to the general statutes.

Two-thirds of the States have statutes which require geographic representation on district boards of health. One State requires such representation through commonly accepted practice without a statutory provision.

¹ Refers to States where provisions are applicable only to some governmental areas or under some conditions.

² One State has regulations governing these items.

There are 23 States in which members of the local legislative body by statute constitute all or some part of the board of health, but in 11 States such representation is limited to certain conditions or areas. In one State this type of representation is established by common practice.

In recent years there has been considerable interest expressed in having the general public represented on boards of health. The questionnaires reveal that 19 States have statutory provisions requiring the general public to be represented, but in 10 of these there are limited conditions under which such representation occurs. There are 8 other States in which representation of the general public is excluded because these States generally have statutory provisions which name specific officials or mem-

bers of the legislative body to the board of health, with no opportunity for the general public to be represented. It is interesting to note that three-fourths of the State health officers commented that there should be representation of the general public on local boards of health.

One-third of the States have statutory provisions permitting the local health officer to serve as a regular member of the board of health. Twenty-one States permit local health officers to serve as ex-officio members of boards of health. However, the service of health officers as regular or ex-officio members of boards of health is usually limited to certain classes of local areas or only to certain conditions.

It is obvious from the foregoing that there is little uniformity among the States as to the

membership representation on local boards of health. Frequently, more than one of the groups mentioned are represented. Legislative members, local administrative officials, and the medical profession are the most prevalent groups included in membership. In addition, the majority of the States include the health officer as either a regular or ex-officio member of the board, although there are at least 20 States in which he is not a member of boards serving at least some local areas.

Other Membership Requirements

Table 3 also indicates that statutes in more than two-thirds of the States require members of boards of health to be residents of the health jurisdiction. In addition, six States have this requirement in practice. Statutes in about one-quarter of the States require that board members be eligible to vote in the jurisdiction, while six other States make this a practical requirement. Statutes are generally silent with respect to the requirement that board members be taxpayers in the area.

Term of Office

Wide variation exists in the term of office for members of local boards of health, although

statutes in most States prescribe the term. About one-third of the States specify terms of 2 years or less. Ten States have statutes calling for an indefinite term of membership for all or some local boards of health. It should be pointed out that a State frequently has statutory provisions which specify a different tenure for members of local boards serving counties and for those serving cities. More than half the States have statutes which provide that the expiration dates for terms of board members shall be staggered so as to give some continuity to the board.

Procedural Requirements

Statutes in 29 States specify that boards of health shall hold regular meetings and indicate the frequency of such meetings, although such provisions are of limited application in 11 States. Predominantly, meetings are held monthly or quarterly, with the latter taking some precedence over the former interval. Slightly more than half the States have statutory provisions establishing a procedure for calling special meetings of boards of health.

Statutory specification of minimum frequency of board meetings was favored by three-fourths of the State health officers. The majority stated that legal provisions should pre-

scribe the minimum number of meetings, with provisions for special meetings whenever local conditions demand.

The data indicate that boards of health are required to have a quorum by statute in 18 States and by generally accepted practice in 9 other States. Only 15 States have statutes specifying that deliberations of boards of health be governed by bylaws. In addition, there are four States in which the actions of boards are so governed in practice.

In 20 of the States members of local boards of health are entitled to travel expenses either by statute or by commonly accepted practice. In 14 States they receive per diem by law, and in four other States by accepted practice. In only eight States are members of local boards of health entitled to receive salaries.

Appointment of Local Health Officers

Many States have more than one provision for the appointment of health officers. The methods of appointment are associated generally with the methods for establishing local health departments. Some statutory provision for the appointment of local health officers exists in every State, although such provisions are frequently limited in their application to certain areas or conditions. Table 4 indicates that local health officers serving units other than districts are usually appointed by the lo-

cal board of health, the local legislative body, or the State health officer. There are 20 States in which either the State board of health or the State health officer may appoint certain local health officers. However, this power is usually limited to instances in which the regular or local appointive machinery breaks down.

Health officers serving districts are appointed under statutory provisions by the district board of health in 28 States and by the State health officer in 7 States. In addition, there are five States in which district health officers are appointed by the State health officer by accepted practice. Local legislative bodies seldom appoint district health officers, and appointment by a local administrative official was not found.

Twenty-nine States have statutory provisions for the confirmation of the appointments of health officers, while nine other States follow this procedure in practice. Generally, the State health officer, State board of health, or the local legislative body is delegated the authority to confirm the appointments of local health officers. Confirmation of the appointment of district health officers occurs infrequently, but where confirmation is required the State health officer or the State board of health is usually delegated this responsibility.

The consensus of State health officers is that the local health officer should be appointed locally—either by the board of health or the legislative body. However, 28 indicate that his ap-

pointment should be confirmed by the State health officer. Twelve others recommend that he should be required to meet specifications of the State health department, but that the appointment should not actually be confirmed. Eight believe that he should be appointed by the State health officer or State board of health.

Other Provisions for Health Officers

In seven States local health officers serving some types of local health departments become deputy State health officers by law. In eight other States they hold this position through commonly accepted practice.

Statutes in nearly three-fourths of the States provide that at least some cities, towns or townships may retain a local health officer even though the governmental area itself becomes part of a larger health jurisdiction. The comments clearly indicate that State health officers generally oppose the retention of a legally designated health officer in minor governmental areas of a health jurisdiction. It is the opinion of State health officers that the health unit director should exercise the authority of health officer throughout the health jurisdiction and that any other health officers should be subordinate to him.

By statutory provisions, local health officers serving at least some types of local health departments are selected in 16 States under a merit

system. Seven additional States have regulations to this effect, and eight States select local health officers in this manner by practice. In those States in which the law specifically indicates the manner in which local health officers shall be appointed, such procedures may preclude his selection under a merit system. Thirty-nine State health officers indicate that it is desirable for local health officers to be selected under a merit system.

There is wide variation in the statutory provisions for term of office for local health officers and equally wide variation in the accepted practice where no statutory requirements exist. The questionnaires indicate that local health officers most frequently have either a 2- or 4-year term of office. There has been a definite trend in recent years for the term to be made indefinite. In several of the States with statutory provisions specifying the term of office there is actually no reappointment of health officers at the intervals specified.

Qualifications Required

More than two-thirds of the States require by law that local health officers possess the qualifications for a State license to practice medicine (table 6). In five States this requisite is specified by regulation, and in two States the requirement is by common practice. Most of the States with stipulations that the health officers

qualify for a State license actually require them to secure the license. Only 11 States make statutory provisions for temporary licensure of health officers, one additional State provides for such licensure by regulation, and two States do so by practice.

The laws of 31 States require at least some health officers to serve full time though such statutes are generally limited in their application (table 6). In addition, three States have regulations requiring full-time service and five States require it by accepted practice. Frequently, the regulatory requirement or practice of requiring full-time service of local health officers is related to the health department's eligibility for State financial assistance.

Twenty-seven States require public health training of local health officers serving at least some types of health departments. Such requirement is twice as frequently specified by statute as by regulation. Usually, the provision is general, not specifically stating the amount or kind of training required.

Only 7 States require by statute that health officers have experience, but 10 States have regulations requiring experience. The present shortage of qualified health officer personnel has made difficult the enforcement of experience requisites in existing statutes and regulations.

The majority of State health officers were opposed to defining qualifications of local

health officers in statutes. The major objection indicated was that specificity in this matter makes conditions too rigid and hampers the recruitment of personnel. Many indicated that qualifications, if defined, should be set forth in State health department regulations rather than in statutes. A number favored a flexible system, with required training and experience commensurate with the size and complexity of the individual health unit. Nearly all State health officers felt that local health officers should be legally licensed physicians. Several State health officers indicated that such items as personality, administrative ability, interest in community health, and ability to get along well with people are more important than specified training or experience backgrounds.

Responsibility of Local Officers

Table 7 indicates that State statutes and practices hold local health officers responsible to several types of governmental authorities. In many instances the health officer is responsible to more than one authority and is frequently responsible to some authority other than the one which appointed him. In most cases when dual responsibility exists, the health officer is responsible to some local authority and to the State health officer. Table 7 indicates that the local health officer is most frequently responsible to

the local board of health or to the State health officer.

The data also reveal that district health officers are infrequently responsible to the separate governmental areas comprising their district, but are usually responsible to the district board of health or to the State health officer.

Governmental Basis of Health Units

For several years health experts have been interested in the types of local governmental areas which may establish health departments. There are now 42 States which have statutes making it possible to establish single county health departments. The six States which have no legal provisions for establishing single county health departments are located primarily in the New England area where the county as a local governmental area has practically no meaning. The establishment of single county health departments is mandatory in four States. Laws governing the establishment of city health units are in effect in 44 States and such units are established in common practice in 1 other State. In eight States it is mandatory for all or some cities to establish local health departments, while in four States cities are not permitted to establish separate health departments.

The fact that most counties in the United States have insufficient population and financial resources to meet the high costs of maintaining a separate local health unit, plus the shortage of qualified health officers, has spurred the development of district health departments to serve more than a single local governmental unit. Legislation is usually necessary to permit local governmental areas to combine and form a district for the operation of a health department. There are now 34 States which have statutes permitting 2 or more counties to form a multicounty health department; in 2 States such districts have been formed without specific legal authority. There are 27 States which have legislation permitting the creation of city-county health departments, and 5 States have established this type of district in practice without specific statutory authority. These foregoing two types of district health depart-

ments are the most prevalent, but statutes exist in several States which permit the formation of other types of districts. The laws of 15 States permit multicounty units and a like number permit multitown or multitownship units; 11 States permit the combination of cities and townships; 10 States permit the combination of counties, cities, and townships; and 8 States permit the combination of counties and townships. In addition, a few States have established these more unusual types of districts in practice although no statutory authority exists.

Methods of Establishment

There are several methods by which local health departments may be established. Local health departments serving either single units of government or those serving multiple governmental areas are most frequently established through action of the local legislative body or, in district areas, of each constituent legislative body within the district (table 9). The second most popular method is by referendum of electorate. This method is permitted by law in 16 States with respect to single governmental

areas and in 17 States with respect to multiple governmental areas. This plan normally requires that a certain percentage of electors submit a petition asking that the question of creating a local health department be placed upon the ballot. Local health units of either the single-unit type or district type are infrequently established by action of State health officers or State legislatures, although such methods are permitted by law in several States.

It is the opinion of State health officers that the establishment of local health departments is a matter for local determination. A few State health officers indicated that State legislative action should make them mandatory. Local legislative action or local referendum, or a combination of the two, were deemed by State health officers as the most expedient methods for initiating action to establish local health departments. The same general methods were favored for the establishment of district health departments. More State health officers, however, felt that in order to foster some logical plan for state-wide districting, such departments should be subject to the approval of the State health officer.

Dissolution of Local Units

Statutes usually fail to specify the manner in which local or district health departments may

be dissolved. In 15 States there are no statutory provisions for the dissolution of health units. Action by the local legislative body is the most frequent method employed to dissolve a health department; 15 States have such statutory authority with respect to single governmental units and 13 States with respect to multigovernmental units. Such action is taken by commonly accepted practice in 13 States for single county units and in 11 States with respect to district health departments (table 10). Referendum of the electorate is the second most popular method for dissolving local health departments, with 6 States making this method applicable to single governmental areas. Seven States provide by statute for the dissolution of districts by referendum action of the electorate of the whole jurisdiction while 6 States provide for referendum of electorate of each constituent area. In several States it is most difficult to dissolve a local health department once established.

State health officers feel that dissolution should be by the same procedure as establishment. Several indicated, however, that a health department should be in operation for at least a reasonable period of time before dissolution should be permitted. Many who indicated that establishment should be by either referendum or local legislative action were of the opinion

that dissolution should not be permitted without referendum. The majority of State health officers felt that the desirability of withdrawing from a district should be determined by each governmental unit. However, they also felt that provisions should be made for a waiting period, or a period following notification of withdrawal, to allow for adjustment in the remainder of the unit.

Table 11 indicates that only 4 States require all governmental units within a county or district health jurisdiction to join the health department. There are 10 States in which statutory provisions permit any type of city to remain outside county or district health departments; 10 additional States permit cities of specified population size to do so, and 7 States permit cities to remain outside the county or district unit if they have a health department of their own. There are a few States in which towns may also remain outside the county or district health department. On the other hand, almost three-fourths of the States permit cities and towns to join the county or district health jurisdiction,

² In 1 State mandatory staffing is required of districts by statute and of other local health departments by practice.

22 States; 5 additional States require such an arrangement by commonly accepted practice.

Only 5 States have statutory limitations as to the number of governmental areas which may combine to form health districts. Also, such limitations are infrequently imposed in practice.

State Financial Assistance

There has been some interest in recent years in the development of criteria which local health departments should meet in order to be eligible for financial assistance from the State. Such criteria generally include mandatory staffing requirements. Table 12 indicates that such staffing requirements are specified by statute in six States and by regulation in four others. In practice, there are 11 additional States which require local health departments to employ certain types of personnel.

A second criteria involves basic services which local health departments are required to render. Nineteen States have some requirements with respect to basic services, but in only 12 States are they generally applicable and in those they are usually applied in practice rather than by statute.

Local health departments infrequently are required by statute to submit a plan of action. However, nearly one-third of the States require such plans in practice. If a plan is required of the local health department, it is generally subject to approval by the State.

Criteria for State financial assistance sometimes include a minimum population which the department should serve, but only nine States require local health departments to serve a minimum population.

Summary

While most States have some statutory provisions for the creation of boards of health, the appointment of local health officers, and the establishment of local health departments, there is wide variation between the several States in the details of the statutory provisions. Basically, statutes provide for boards of health either appointed by or composed of members of the local legislative body, or local administrative officials. These boards generally have the responsibility of designating the local health officer who directs the local health department program. The health officer is usually responsible to the authority which appointed him, but, in addition, may be responsible to other local authority and particularly to the State health officer.

Most States have statutory provisions which permit the establishment of county or city health departments through action of the local legislative body or through popular referendum. Only about three-fourths of the States, however, have such legislation permitting the establishment of health districts serving more than a single local governmental area.

Abatement of Stream Pollution Caused By Industrial Wastes

By ROLF ELIASSEN, D.Sc.

INDUSTRIAL wastes, varied in nature and potent in strength, have been with us for a long time. But in recent years they have been increasing in volume and variety at a rapid rate.

Legislation is pressing industry and municipalities to abate the pollution of streams by controlling or treating their wastes. The times call for rational, economical decisions. To make them, every sanitary engineer needs to know a great deal more about the fundamentals of the sanitary engineering profession and its relationship to industrial wastes.

Throughout the years, sanitary engineers and sanitary scientists have developed and put into practice treatment processes involving chemical, physical, and biological phenomena characteristic of domestic sewage. Domestic sewages do not differ much, unless mixed with industrial wastes. And many civil engineers, with only a rudimentary knowledge of design criteria for treatment plants, can adopt the regulations of State health departments and proceed with plant designs. Through the efforts of sanitary engineers in these departments, design criteria have been made sufficiently liberal to insure adequate treatment under average conditions.

Dr. Eliassen is professor of sanitary engineering at the Massachusetts Institute of Technology and served as an advisory member of the United States delegation to the Fifth World Health Assembly in May. This paper is based on a presentation before the American Society of Civil Engineers, October 23, 1951, at New York City.

Changing Needs

In recent years special problems have put new demands upon the ingenuity of sanitary designers and operating personnel. This is particularly true in cities having appreciable proportions of industrial wastes mixed with domestic sewage. Research has led to more economical and more easily operated processes, and many excellent treatment plants are in operation. Furthermore, many sanitary engineers are set to meet new demands from industry. But it must be conceded that rule-of-thumb engineering no longer applies successfully to the design of treatment plants for sewage and industrial wastes. This method may have done a good general civil engineering job for municipalities, but it may fail to abate water pollution if it is applied to industrial wastes.

Rarely will wastes from similar industrial establishments be exactly the same from plant to plant. They may fall into similar categories, but the concentrations and individual components may be far apart. Each waste requires special analysis and an approach based upon a sound knowledge of each unit operation which may be applicable in a treatment process. Rule-of-thumb approaches may lead to plants which may not operate properly or may not even accomplish the assigned task.

Engineer Cooperation

Many industrial wastes can be eliminated by process revisions within the industrial plant. In many cases, this is within the province of the chemical engineer. The field of wet-process

engineering, particularly within chemical and allied industries, is the province of the chemical engineer. This profession is gradually coming to realize that cutting down the volume and strength of industrial wastes is their responsibility.

Sanitary engineers must cooperate with chemical engineers in this work, and it is necessary for them to learn enough about the chemical engineering field to make that cooperation intelligent and beneficial. After chemical engineers have completed process changes within the limits of economics, many plants find it necessary to discharge liquid wastes having sufficient concentration of pollutants to require treatment. The determination of the economics of process changes versus treatment of wastes, either individually or when mixed with municipal sewage, can best be accomplished by close cooperation between chemical engineers and sanitary engineers.

The sanitary engineer has wide experience with chemical and biological processes for the removal of dilute concentrations of solids, both organic and inorganic, from liquids and the processing of these solids for ultimate disposal. His is also the best qualified profession to deal with problems of stream sanitation, including the biochemical processes of stabilization of organic matter in streams. Toxicity of the constituents of industrial wastes to the biological population of streams has been the subject of extensive studies by sanitary engineers and sanitary scientists. One of the most important contributions of the sanitary engineer to the economics of waste treatment is his knowledge of the capacity of municipal sewage treatment plants and of streams to absorb organic pollutants. Thus, his education and experience can be utilized for the evaluation of the extent of treatment required before industrial wastes may be discharged into municipal sewers or directly into streams and for the design of plants to accomplish this treatment.

Tailor-Made Solutions

There can be no pat formulas, no magic keys to success, for solutions to the hundreds of categories of industrial wastes which must be treated and bodies of water which must be pro-

tected. The quality of sanitary engineering service will be judged by the thoroughness with which each problem is approached and the ingenuity with which economical processes are developed and effective treatment plants designed. In most cases, satisfactory solutions can only be attained by complete chemical and physical analyses of the wastes, which are correlated with existing information in the literature of sanitary engineering and followed by laboratory and perhaps pilot plant tests. The day of reference to time-worn design criteria for a general class of wastes is past. Each problem demands particular attention and a tailor-made solution.

Each unit operation of the sanitary engineer must be based on the application of sound principles of the fundamental sciences of chemistry, biology, physics, and mathematics if effective and economical processes are to be developed. Therefore, the sanitary engineer must not only be qualified by his basic education in civil engineering to conceive and construct hydraulic structures, but he must also be well educated in the sanitary sciences built upon biology and chemistry. The major difference between a chemical engineer and a sanitary engineer is the primary reliance of the former on physical and chemical phenomena in his operations, whereas the sanitary engineer has command of biological as well as physical and chemical actions in the unit operations employed in sanitary engineering processes. In some instances, the sanitary engineer may be classified as a biochemical engineer to distinguish him from the chemical engineer.

Therefore, sanitary engineers of the present and of the future must be far ahead in the field of biochemistry. They can only achieve this knowledge by a concentrated program of scientific education in colleges and continued study while engaged in the practice of sanitary engineering. The sanitary engineer cannot go it alone. He must have qualified sanitary chemists and sanitary biologists as members of his team. With the right combination of talents in these three major realms of sanitary engineering, this team can give distinguished service to industry and government in the abatement of stream pollution by the control and treatment of industrial wastes.

Research Uses

This team of engineers, chemists, and biologists must not only be devoted to the solution of existing problems by known unit operations in the design and operation of treatment processes, but must also be constantly striving for effective utilization of the phenomena of the fundamental sciences. Research in sanitary engineering has led to the present high standards of treatment of sewage and industrial wastes. The field for research is open for the development of rapid methods for the fermentation of organic wastes by aerobic and anaerobic processes. Witness the great strides being made by biochemists and soil microbiologists in the fermentation processes employed for the production of antibiotics. In a few short years, they have succeeded in increasing rates of production tenfold. Can we say the same for our biochemical processes? We should be and must be able to accomplish rapid fermentation so that processes may be economical and widely applicable to many wastes now outside the realm of treatment by our various unit operations.

We are necessarily faced with expanding horizons for our research workers who must incorporate many of the unit operations utilized by chemical engineers, such as absorption, extraction, distillation, evaporation, and others. The sanitary engineer and the chemical engineer must cooperate in developing processes utilizing the best of knowledge and experience from both professions.

Conclusion

Our keenest brains must be applied to the problems encountered in the treatment of industrial wastes and the abatement of stream pollution. Engineers must also divest them-

selves of any lingering illusion that they can quietly go their own fixed ways of applying empirical formulas to categorical problems. But we must be prepared to be patient and persistent in the pursuit of knowledge of the fundamental sciences to be applied to the critical problems of so very many different industrial wastes. We cannot afford to be thrown off balance by the demand for quick answers and simple methods. Proper solutions take time and cost money. Therefore, consulting engineers must be prepared to educate their clients to the need for sufficient funds and time to do the job thoroughly.

Allies in the fields of chemistry, biology, and chemical engineering must team up to make the changes deemed economical and necessary within the plant and then to apply their joint talents to the treatment of the liquids which must be discharged to streams of municipal sewers and treatment plants. Through knowledge of the principles of physical, biological, and chemical unit operations, and of stream sanitation, sanitary engineers must demonstrate that they can by economical design and operation make streams safe from the standpoint of public health, recreation, and beneficial use of water for the industries and cities downstream.

The key to future success lies in continued development through the application of the fundamental sciences. The cost of failure of the rule-of-thumb engineer to understand these fundamentals may be staggering. Therefore, let the sanitary engineer team up with the chemist, the biologist, the physicist, and the chemical engineer, and the future will hold great promise for more economical treatment processes and effective abatement of stream pollution.

The Movement Toward Sound Drug Therapy

1952 marked the celebration of the 100th anniversary of the founding of the American Pharmaceutical Association. It marked, as well, a step toward eliminating the confusion existing in the multiplicity of drugs available to physicians, dentists, and pharmacists. A new handbook, synthesizing the best available in modern drug therapy, was completed. "Basic Drugs: U. S. Public Health Service Hospitals and Clinics" will be used by the 18 hospitals and 22 out-patient clinics of the Public Health Service as their standard for the known therapeutic agents in the prevention and treatment of illness. The accompanying paper was presented, with somewhat more emphasis on the role of the pharmacist in the hospital, before the American Society of Hospital Pharmacists at the annual meeting of the American Pharmaceutical Association in Philadelphia on August 21, 1952. Reviewed below is the trend of professional criticism appearing in medical and trade journals over several decades.

1930 "The hospital . . . should afford unusual opportunities for enhancing rational drug therapy. There particularly may products be submitted to critical inspection. As Sollmann so pointedly remarked at the recent Congress on Medical Education [February 17-19, 1930], the 'evaluation of therapeutic remedies is not usually among the features to which hospital authorities point with just pride of achievement.' The hospital drug room, which reflects directly the medicinal requests of the staff, has hardly kept pace with the modernization of other departments. . . ."

—from an editorial in the *Journal of the American Medical Association*, May 31, 1930, p. 1764.

1941 "There is far too little correlation between pharmacology and drug therapy at the bedside. . . . As students and, subsequently, as practitioners they [physicians] had, and have the ordeal of trying to learn myriads of drugs. . . . Such thinly spread teaching and learning about hosts of drugs permeates the whole curriculum and medical practice in spite of available scientific criteria for charting drug actions in the clinic which make it possible, in most instances, to shun useless and irrational therapy. The results are particularly reflected in notoriously disreputable pharmacy stocks. . . ."

—from "Rational Drug Therapy in Hospitals" by Drs. M. S. Daoley and E. C. Reifstein in *Hospitals*, January 1941, p. 42.

1949 "A fundamental requirement to successful treatment is that the physician have the clearest possible understanding of the remedial agents that he prescribes. This is difficult at best, and is rendered increasingly difficult with multiplication of agents that are nearly but not quite equivalent. Each may show minor differences, which may or may not be practically important, but which are difficult to learn if he spreads his experience too widely and therefore too thinly. . . . There is another side to the argument, however, for few if any therapeutic agents are ideal. Improvements, increased efficiency, fewer side actions, and lower toxicity should be sought for. Skillful experimentation in this direction should be encouraged, not obstructed, but this thorough experimentation should precede the introduction into medical practice. It were better, much better, for medical practice . . . if modifications which do not offer substantial advantages were shunted into the discard before they see publicity and add to the confusion of practitioners."

—from a report of the Council on Pharmacy and Chemistry, American Medical Association, *Journal of the American Medical Association*, February 5, 1949, p. 378.

An Objective Approach to Drug Therapy

By J. SOLON MORDELL, B.A., Ph.G., and C. K. HIMMELSBACH, M.D.

In April 1952, Paul deHaen reported on pharmaceutical products introduced in the years 1948 through 1951. His report was based on a survey he made of trade and medical journals (1). The 1951 data are illustrative of the preceding 3 years. Among the 322

pharmaceutical products introduced by 86 manufacturing firms in 1951, there were 35 different single chemicals, or about 11 percent of the total. Also, deHaen found 74 instances of duplication of single chemicals—23 percent of the products introduced. And of especial note is this: There were 211 compounded items—66 percent of the 322 total different products introduced. In addition, there were 120 new dosage forms.

Here is telling evidence of how the word "new" has been abused in the field of drug

therapy. Such abuse calls for a distinction between what is really "new" in the sense that penicillin was new in 1943 and that which is a mixture of known drugs marketed under a new name or a duplication of the "new" drug under other names.

Without knowing at what rate drugs become obsolete and unavailable, we are convinced that the net effect is the addition of more and more drugs each year. Thus, discriminate selection becomes increasingly difficult by virtue of numbers alone, and the state of confusion is compounded.

With this vast numerical growth, and the rapid progress in therapeutics—for example, cortisone, aureomyein, chloromycetin, terramycin, isoniazid, in but a few years—there comes the need for improved procedures for clinical assessment. The problem is that of devising the best method whereby the physician and the dentist may be assisted in the difficult task of selecting suitable agents from the multiplicity of drugs and drug preparations which confront them.

The professional interdependence of medicine, dentistry, and pharmacy has been recognized for a long time. We have observed, in the Public Health Service, the development of a wholesome working interrelationship among the three sciences in their common search for an objective approach to sound drug therapy and to uniform drug nomenclature. Early in 1953, the Public Health Service will release "Basic Drugs: U. S. Public Health Service Hospitals and Clinics" (2), a handbook of drug therapy which is in every sense a significant achievement in meaningful teamwork. The climax of 4 years' cooperative study, its publication represents a noteworthy advance in

Mr. Mordell, senior pharmacist, in the Division of Civilian Health Requirements of the Office of the Surgeon General, Public Health Service, was until January 1951 chief of the pharmaceutical service of the Public Health Service out-patient clinic, Washington, D. C. Dr. Himmelsbach is the medical officer in charge of the clinic, which is under the direction of the Division of Hospitals, Bureau of Medical Services.

the satisfying exercise of professional cooperation in trying to make some order out of a confused situation.

Can some order be achieved? How?

Valuable sources of information are available in the standard pharmacological texts and in "New and Nonofficial Remedies" of the American Medical Association; "Reports of the Council on Pharmacy and Chemistry of the American Medical Association"; "Accepted Dental Remedies" of the American Dental Association; and "Useful Drugs" of the Council on Pharmacy and Chemistry of the American Medical Association.

Formularies and other types of drug listing have been individually compiled in many hospitals. However good these listings may be for the specific purpose for which they were designed, many serve mainly as convenient references to indicate the items available in an individual institution. Often, they lack the important features of selectivity and simplification based on fundamental scientific clinical pharmacology. Furthermore, they frequently fail to include a base—a point of departure, a set of criteria—so necessary for an orderly approach to sound drug therapy.

"Standardization"

We hesitate to use the word "standardization" because to many it immediately connotes rigidity. It is therefore important to stress the fact that any plan in the direction of rationalization of drug use must be flexible, even though it does require adherence to certain fundamental principles. If this one concept is not understood and kept indelibly in view, no such plan can be effective in operation: it would lack effectiveness, for our purpose, because pharmacology is a dynamic field in which important changes may and do occur rapidly; it would not work because compulsive restriction to standards leads to defeated initiative and stultified thinking.

The obvious approaches to discriminate selection of drugs would appear to be to develop and keep alive an up-to-date standardization of basic clinical pharmacology as the keystone of drug therapy; and to enhance closer profes-

sional working relationships among the pharmacist, the physician, and the dentist.

Trend Toward Objectivity

One of the earliest, if not the earliest, organized programs which aimed at collaboration with the physician in the objective selection of drug agents was conceived in 1927 in Syracuse, N. Y. Dr. M. S. Dooley, then director of the department of pharmacology of the Syracuse University College of Medicine, and now emeritus professor, inspired and guided in that early pioneering action to clear up what was a chaotic situation.

Dr. Dooley's plan was set in motion at Syracuse University Hospital in 1932 when the idea of hospital pharmacy practice in association with a pharmacy committee was relatively new. As time passed, more hospitals adopted the idea until today it is accepted by many institutions as an integral part of their professional operations. A significant portion of the historic 1937 "Report of the Committee on Pharmacy" of the American Hospital Association was related to the experience at Syracuse in improving the whole field of drug therapy.

A similar reorganization plan of drug therapy procedure was instituted in the early thirties at New York Hospital in Cornell University Medical Center, New York, N. Y. Publication of their therapeutic conferences in the *Journal of the American Medical Association* and in book form has contributed much to the literature on this subject.

Handbook of Drug Therapy

Late in 1948, the Division of Hospitals in the Public Health Service Bureau of Medical Services initiated the preparation of a handbook which would embody primarily the principles of a sound but flexible system of drug therapy in the 18 hospitals and 22 out-patient clinics now administered by the division. The final handbook would in no way be limited to a list of items in the manner of the traditional formulary. The goal was improved therapy—a goal to be accomplished by cooperative effort which would discredit any implications of interference with personal prerogative.

Thirty-four Public Health Service officers, professionally representing medicine, dentistry, and pharmacy, contributed to the finished text of the new handbook, "Basic Drugs: U. S. Public Health Service Hospitals and Clinics." The pharmacy committee at the Public Health Service out-patient clinic in Washington, D. C., spearheaded the project with close support from the pharmacy committees of the Public Health Service Hospital in Baltimore, Md., and of other Service hospitals. Also, authorities in a number of leading universities and teaching hospitals were consulted.

The main objective of the study was to select the best, the simplest, the fewest, and the safest medicines currently needed in the prevention, diagnosis, and treatment of illnesses. In accomplishing this, the chief task often was one of eliminating duplication and overlapping of items rather than that of sorting out the good from the bad or indifferent. This was a difficult and time-consuming process, especially when it sometimes involved, as it did, giving up a favorite drug which had been successfully utilized over a period of years. As expected, most of the difficulties arose in those areas where fundamental knowledge was not truly adequate and where differing views were advanced by the "experts." In certain of such areas, the drugs selected represent compromises.

Selection Criteria

The following criteria were utilized in the selection of drugs for the handbook:

1. The primary criterion was therapeutic efficacy. Within this criterion, preference was given to items listed in "United States Pharmacopeia," "National Formulary," "New and Non-official Remedies," and "Accepted Dental Remedies."

2. Unnecessary duplication was avoided.

3. Drugs of secret composition were not considered.

4. Mixtures were included only when they provided substantial advantage over the individual components.

Barbiturates: An Example

In considering the scope of drugs to be selected, attention was given to the drugs repre-

sentative of the various pharmacologic or therapeutic groupings and the clinical needs to be met.

Typical of the selection process is the sequence of activities which led to the choice of certain barbiturates as basic hypnotics and sedatives:

1. The barbiturates, as a class, were compared with other U.S.P., N.F., N.N.R., and A.D.R. hypnotics and sedatives. It seemed clear that for general usefulness, the barbiturates represent the surest, simplest, and safest of the hypnotic and sedative drugs. Their range of usefulness extends from mild sedation through spasmolysis and hypnosis to general anesthesia. The therapeutic range of safety is relatively great, most of the unfortunate sequelae being deliberate rather than accidental.

2. Since the nature and degree of effect are largely a function of dosage, the truly basic differences which exist within this class relate to the rate at which they are rendered inactive in the body. This, in turn, affects their duration of action. From the standpoint of therapeutic need, clinicians agreed on four ranges of action: Short, intermediate, long, and ultra-short (anesthetic).

3. Selection of the best agents to meet these needs became the next stage in the process. After much deliberation over the qualities, reliability, official status, usage experience and related aspects, the choices in the short and long ranges were secobarbital and phenobarbital, respectively. Thiopental was the obvious choice for the ultra-short representative. However, most of the discussion centered upon the selection of a barbiturate of intermediate duration of action. After the pharmacy committee discussion narrowed the field to two drugs, the opinions of specialists and consultants were requested. It became clear that custom had been the determining factor in most instances. Since the balance in terms of familiarity of usage and in certain aspects of consistency of action seemed to favor pentobarbital, it was selected as the basic barbiturate for intermediate duration of action.

4. The next step was to prepare the material on this subject for incorporation into the manual. The pharmaceutical, chemical, pharmacologic, toxicological, and dosage information considered essential to the clinician, pharmacist, and nurse were prepared and presented to the pharmacy committee for comment, criticism, and suggestions. When a draft had been agreed upon, it was duplicated and given to the staff as a trial guide, and the pharmacy stocks were adjusted in line with the agreement. After a brief trial period of several months had shown that therapeutic needs were adequately met, the material was made available for joint consideration with the pharmacy committee of the Public Health Service Hospital in Baltimore. Subsequent to agreement with that committee, the material, along with the remainder of the manual, was sent to each major clinical facility of the

Public Health Service, and to national authorities, for their consideration.

5. The suggestions and criticism resulting from these reviews were integrated into the final product. This, in turn, was carefully scrutinized by the headquarters staff with especial reference to the actions which had been taken on the comments and suggestions received from the field stations.

Thus, in the processing of the material and the selection of the basic drugs in the class of barbiturates, as well as in all other classes, most of the clinicians in the Public Health Service have had an opportunity to have their views receive appropriate consideration. Hence, the end product truly represents one achieved by joint action and agreement.

At some future time, a significant number of physicians may find that one of these barbiturates doesn't meet normal expectations. That kind of opinion usually has meaning because it is formed from adequate, first-hand observation. It is an opinion which cannot be formed easily or reliably when a large number of like drugs are used without regard to relative advantage and the unnecessary duplication which may exist. It gives the pharmacy committee and the clinician a basis for reevaluating the drug, perhaps leading them to seek a replacement, or possibly a supplementary drug. They may find that the agent in question, despite its shortcomings, should be retained because it is the best available drug for the purposes required. Thus, the whole approach is kept as scientific, objective, and independent as this field permits.

The Scope of Basic Drugs

The treatment given the barbiturate group is illustrative of the other groups. The items finally selected then form the basis for the pharmacy supply of drugs and drug preparations. Except for nonbasic drugs temporarily stocked for investigational or other special committee-authorized purposes, the drug supply consists of the basic agents.

The field of drug therapy being what it is, additions or deletions are to be expected, and the clinician is encouraged to propose changes. A request for an addition is placed on the agenda for a forthcoming pharmacy committee meeting. When the prescriber finds it necessary

to use the drug before the scheduled committee discussion, a small supply is obtained for the particular patient if none of the available basic drugs is found adequate and if there is no immediate, serious objection to the proposed drug. At the meeting, the clinician requesting the drug presents the reasons for wishing to use it. After a general discussion, the pharmacy committee may vote for acceptance, denial, or a trial period of tentative acceptance.

This procedure does several things:

It maintains freedom of action for the prescriber within the framework of the scope of basic drugs.

The prescriber is encouraged to think through the reasons for wishing to add drugs or to drop previously accepted ones. If a proposal cannot stand on its merits in a free discussion among colleagues, there should be little regret about its demise.

The pharmacist, as a committee member and consultant in drug therapy matters, is given greater opportunity to apply his professional competency.

The adopted coverage, as presented in the new handbook, provides a standard of comparison for the evaluation of new therapeutic agents.

Finally, the adoption of a basic range of therapeutic agents and the procedure for going beyond it help provide the patient with the best in the way of established drug therapy.

Two examples may serve to illustrate the validity of this approach:

Surgeons have need for a safe, reliable, orally effective relaxant of skeletal muscle. A new drug reputed to have such effect was proposed for trial on certain patients selected with the cooperation of the chief of the surgical service. Disappointing results were reported about a year later to the pharmacy committee with a recommendation against stocking the drug in the pharmacy.

Surgeons also have need for a good sympatholytic agent. Here, too, they tried out the agent of their choice and reported the results. In this instance, however, they were impressed with the value of the drug in selected cases. Their recommendation that it be stocked as a nonbasic drug for such use and for future reevaluation as a possible basic drug was accepted.

Nomenclature

Drug names were another problem in the efforts to devise a procedure for promoting sound

drug therapy. There is the professional and economic problem of multiple drugs and drug preparations which differ in name only. There is also an element of safety to be considered.

Is it not as important to have a standard terminology for drugs as it is to have a standard terminology for names of diseases, for causes of death, and for the anatomy of the body? Accurate communication with respect to drugs is certainly of highest importance here and extends beyond that which exists between physician and pharmacist.

Various texts, devised as aids to medical terminology, have been prepared for the use of medical record librarians. But when it comes to drug names, the medical record librarian has met with frustration. The situation is of even greater concern to the nurse, who has to administer drugs. With these problems in mind, the following principles of drug nomenclature were adopted:

1. Official drugs listed in the "United States Pharmacopeia" or in the "National Formulary" are referred to by their official English titles. Examples are:

Hydrous wool fat—*not* lanolin.

Methyl salicylate—*not* wintergreen oil, *nor* gaultheria oil, *nor* betula oil, *nor* sweet birch oil, *nor* teaberry oil.

2. Nonofficial drugs listed in "New and Nonofficial Remedies" of the American Medical Association and in "Accepted Dental Remedies" of the American Dental Association are referred to by the generic, nonrestricted name assigned by the drug councils of the two professional associations. For example, chorionic gonadotropin, the N.N.R. generic name, is used instead of the numerous names listed for this agent.

3. In some instances, an official drug such as naphazoline hydrochloride having the trade name Privine Hydrochloride, or an N.N.R. drug such as lidocaine hydrochloride with the trade name Xylocaine Hydrochloride, is produced by one manufacturer and is obtainable only under the trade name. Such drugs are referred to in the handbook by the official name or by the N.N.R. or A.D.R. name, as the case may be, and are followed by the trade name in parentheses. The trade name is used in hospital prescriptions to avoid ambiguity where orders are given directly to a nurse. It seemed impractical and

pedantic to use the official name naphazoline hydrochloride, for example, when the drug is obtainable only as Privine Hydrochloride. It is especially impractical in instances where ampuls bear the label or imprint of the nonofficial name. Often, the drug later becomes available under the official name or under other trade names. Then the previously exclusive trade name is dropped, and a return is made to the common base: the official name or the generic nonofficial name.

By this attention to drug names, it is possible for all concerned—physician, dentist, pharmacist, nurse, medical record librarian—to speak the same language. Moreover, the pharmacist is able to discharge a professional function for which he is trained, that is, the selection of the best drug from the pharmaceutical standpoint. No longer is there need to overload the pharmacy with many brands of the same drug or drug preparation. And as to therapy, the physician need not be concerned with much more than the selection of the therapeutic agent and the dosage. He decides, for instance, that the patient should have aluminum hydroxide gel in stated doses. The pharmacist is free to select the best available product without having to burden the pharmacy with many brands of the same item.

The Pharmacist

The success of a program of sound drug therapy depends in large measure on the professional stature of the pharmacist. To some pharmacists, as to some physicians and dentists, this type of operation may mean a departure from deeply rooted pathways of thought and action, calling for a new perspective on their part in the handling of drugs. It calls for basic knowledge not only of technical pharmaceutical functions but of drug action and drug use as well and of the differences and shortcomings which may exist among drugs. It means an awareness, for example, that witch hazel water, which would not be included in the basic drug scope, is nothing more than alcohol, water, and a witch hazel aroma—that witch hazel water will do little more than will an aqueous, 14- or 15-percent dilution of alcohol. What is most important is the ability to present

this type of information in scientific and, above all, unobtrusive fashion.

In administration of the program, it should be understood that "Basic Drugs" is not an instrument of rigid control but is essentially the sine qua non for maintaining a coordinated approach to sound drug therapy. The prescriber is encouraged at every opportunity to demonstrate his reasons for wishing to add a drug to the basic list and is not refused a drug merely because it does not appear there. The whole objective will fail if the physician or dentist is in any way discouraged from questioning the existing list. On the contrary, they should be encouraged to be analytically critical. This will serve to improve this tool and to sharpen therapeutic acumen. The goal is improved therapy—not disciplinary control.

Several courses of action are open when the pharmacist who receives a request for a non-basic drug informs the prescriber that the drug is not currently stocked:

The prescriber may ask if a drug of like action is available.

Or the occasion may be such that the pharmacist can take the initiative by suggesting the available analogous drug. The prescriber may decide to use the available drug and then find that it is the equivalent of, or better than, his first choice. Whenever that happens, it is a confirmation of our selection methods.

If there is doubt about the basic drug, the pharmacist may encourage the prescriber to present the drug originally requested to the pharmacy committee for acceptance. If the occasion demands, the pharmacist will offer to secure the nonbasic drug for the patient, subject to approval from the chief of the service, until committee action is taken.

Core of His Activities

After the system is in operation, members of the medical and dental services become familiar with the procedure, and the rest is automatic.

Once the pharmacist is relieved of accumulations of unnecessary drugs, he can then focus his attention on the drugs which he knows represent the core of his activities. He is free to acquire complete knowledge about these drugs and to consider improvements in ways of administering them.

Would this mean less work for the pharmacist? Not necessarily.

Take cough preparations as one example. There are almost as many of these as there are coughers. Under the basic drug approach, the fundamental physiology of coughing was examined and the bases for therapy were determined. Ammonium chloride was selected for its general liquefying and expectorant effect to aid the removal of sputum from the respiratory passages. Codeine was selected to depress the cough reflex when the cough becomes excessive or futile. Finally, potassium iodide, subject to certain contra-indications to its use, was selected for liquefying especially tenacious sputum which has not yielded to other measures. The responsibility for devising suitable vehicles for these agents now resides with the pharmacist whenever their administration is desired in liquid form.

This illustrates a situation calling for additional work by the pharmacist since agents used previously may have been purchased instead of having been prepared in the pharmacy.

The Open-Staff Hospital

How does a system of sound drug therapy operate in an open-staff hospital?

Usually the approved scope of drugs, previously agreed upon by the chiefs of each service in collaboration with the pharmacy committee, is used as the basis for drug therapy on ward service. It is understood that only the basic drugs are stocked in the hospital pharmacy. Nonbasic drugs prescribed for private patients are purchased (for the patient and not for "stock") without delay and in the minimum available quantity. In time, physicians who attend on ward service are able to evaluate the basic drugs used, and, once assured of their soundness, usually employ the same drugs for their private patients. Soon there is a diminishing number of special purchases of nonbasic drugs except for those under investigation.

The critical factors involved in the operation of the system in such hospitals are these: the need for prior agreement on the part of the chiefs of each service; the selection of a physician as guiding hand in the program who is aware of the problems to be tackled and the

objectives to be achieved; and the collaboration of a pharmacist with the same awareness.

Drug Manufacturers

It should be understood that a program of sound drug therapy is directed toward a logical application of drugs in the treatment of illness. The pharmaceutical manufacturer serves an indispensable function in accomplishing that aim. Manufacturers who inquire about the new program are admittedly interested in its effect on their operations, but they are soon convinced that our interest in having an opportunity to assess the new, that is, really new and potentially effective therapeutic agents, equals their interest in bringing the new drugs to our attention. As in all competitive enterprise, here too there is just as much chance for the manufacturer to gain as to lose. Proposed drugs are given every consideration. A drug which is finally adopted after organized, careful scrutiny has the substance and the chance of survival that otherwise may not obtain.

Conclusion

Thus, an attempt has been made to keep the base—the point of departure—not the end, but

the means to the end of the soundest drug therapy available at this time. The degree to which this is successful depends on an appreciation of pharmacology as the basis for sound therapy, of the need to keep the base alive and up-to-date, and of the need for professional coordination of the fields of pharmacy, medicine, and dentistry.

The purpose of the foregoing has been to enunciate a principle of operation which has been found useful, but not to stipulate either method or content in detail. The circumstances brought about by certain existing confusion in the field of drug therapy led to the development of method and content designed to meet particular Public Health Service needs, but it is believed that the underlying principle of this approach is broadly applicable.

Children's Bureau Appointments

The appointment of Elizabeth Healy Ross, M.S.W., to the newly created post of deputy chief of the Children's Bureau and of Melvin Glasser, B.S.S., as special assistant for State and national organization relations on the bureau's juvenile delinquency project, was announced in September by the Federal Security Administrator.

Before coming to the Children's Bureau, Mrs. Ross, a psychiatric social worker, served as consultant to various Federal and District of Columbia agencies, including the National Institute of Mental Health. A member of both the American Association of Social Work and of the American Association of Psychiatric Social Workers, Mrs. Ross was elected a member of the executive committee of the National Conference of Social Work in 1951. She is a member also of the panel on Mental Health of the President's Commission on Health Needs of the Nation.

Mr. Glasser was executive director of the Midcentury White House Conference.

Four Health Education Evaluation Studies

Health education programs are more likely to be effective when objective measures are applied as the program is being developed in order to identify likely barriers to success. By discovering such barriers during the early stages of program development, necessary improvements can be made quickly and at minimum cost. These findings are reported in Public Health Monograph No. 8, "Pretesting and Evaluating Health Education."

The studies reported are: "Application of Pretesting in Health Education," by Andie L. Knutson, Ph.D.; "Pretesting a Nutrition Filmstrip," by Benjamin Shimberg, Ph.D.; "Evaluating a Nutrition Education Program," by Benjamin Shimberg, Ph.D., and Jane S. Harris, M.S.; and "Note on Exhibits as a Health Education Medium," by Mayhew Derryberry, Ph.D.

Approach to Pretesting

A systematic approach to pretesting is suggested by calling attention to several conditions necessary for effectiveness which must be satisfied. While satisfaction of these conditions will increase the likelihood of program success, it does not guarantee program success.

A distinction is drawn by Knutson between critical review of the planning process, evaluation studies of program effectiveness, and objective pretests to identify possible barriers to success. A variety of practical approaches are suggested for anyone who wishes to carry out pretests of educational programs or materials.

Nutrition Filmstrip

An application of the principles and methods of pretesting is illustrated in the development of an informational filmstrip about nonfat dry milk. Shimberg emphasizes the techniques and

Public Health MONOGRAPH 8

The accompanying summary covers the principal findings presented in Public Health Monograph No. 8, published concurrently with this issue of *Public Health Reports*. The authors are members of the staff of the Division of Public Health Education, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and the major universities, and in selected public libraries.

Knutson, Andie L., Shimberg, Benjamin, Harris, Jane S., and Derryberry, Mayhew: Pretesting and evaluating health education. Public Health Monograph No. 8 (Public Health Service Publication No. 212). U. S. Government Printing Office, Washington, 1952. Price 20 cents.

methodology selected to meet the specific problems posed by this filmstrip.

The behavioral pattern depicted in the film was checked to see whether it conformed with the pattern of living of the intended audience.

Tests to reduce reading difficulty and increase human interest were utilized. Personal interviews of a sample of the intended audience revealed where misunderstandings of the text and illustrations could be eliminated. A test copy of the final filmstrip determined its effectiveness in imparting information about nonfat dry milk to women attending a clinic.

Nutrition Education Program

Evaluation of a health education program in terms of behavior is described in a third paper by Shlimberg and Harris. A follow-up study of an educational program about nonfat dry milk was carried out 2 months after the program was presented in a well-baby clinic. Answers to the following questions were obtained: Was the family milk consumption increased? Did the people begin using nonfat dry milk after this program? Did women acquire the information which the program attempted to teach? What attitudes did they have toward nonfat dry milk after the program?

Exhibits

A fourth paper by Derryberry considers these questions: How long will people look at a health exhibit? How much material can be included in an exhibit with some assurance that it will be read?

During the New York World's Fair, trained observers recorded the number of seconds visitors actually spent looking at each exhibit in the Hall of Medicine. Other observers read all the legends of each exhibit and recorded the length of time required to read them. Comparison of these two time-records revealed that as the length of time to read an exhibit increased, the relative amount of time spent on an exhibit decreased.

The findings suggest to exhibitors the need to limit the information they try to cover in an exhibit, if they expect the audience to read the message.

The first two papers in the series, which is continued in the monograph, were published in *Public Health Reports* last year, one in January and one in July.

Sources of Morbidity Statistics

Where do morbidity data come from? What are the gaps?—and what steps should be taken to fill them?

The Third Report of the WHO Expert Committee on Health Statistics presents, among other things, a panoramic review of morbidity statistics sources. Some 24 sources of morbidity data are classified by uses—disease control, program planning, research, etc.; by coverage in terms of population—whether all persons are included, a representative sample, or various types of non-representative samples; by the degree of coverage—whether all or only selected sicknesses are included, and whether disease is reported at a point in time or for a period of time; and by the type of country in which each source is applicable.

The committee recommended study of the sickness survey method as a means of obtaining morbidity data for the general population for health needs. It called for intensive study of means to determine the extent of illness in the general population from data covering selected or specialized populations. Each of the sources of such data—for example, hospital records—is a potential reservoir of public health statistics. The problem is to utilize existing data to obtain a picture of illness in the general population.

The committee made a series of recommendations—covering studies of methods for obtaining data, morbidity terms to be defined, methods of classifying and presenting morbidity data, computing morbidity rates, etc.—to serve as guideposts

for future study and possible action. One of its major recommendations was that “national agencies responsible for health or health statistics establish groups of experts in sampling theory, in the operation of field surveys, and in the analysis of morbidity data within their organization which can utilize survey methods in the investigation of the varied health problems with which such agencies are confronted and make the services of these experts available for consultation throughout the nation and for international purposes.”

Copies of the report may be obtained on request to the National Office of Vital Statistics, Public Health Service, Federal Security Agency, Washington 25, D. C.

Antimalarial Activity of 4,000 Compounds

More than 4,000 compounds were tested at the National Institutes of Health from 1941 to 1951 for antimalarial activity against *Plasmodium gallinaceum* and for toxicity to the chick. These and related data appear in Public Health Monograph No. 9, "A Survey of Antimalarial Compounds."

The report includes a detailed description of the tests employed for antimalarial activity, both suppressive and prophylactic, and the tests for subacute chronic toxicity to the chick. The compounds tested are arranged in chapters according to their presumably important chemical structure. Every chapter contains a series of tables, each of which summarizes the data on compounds in which usually only one part of the molecule has been varied. For each compound the results of the following tests are given: minimum effective therapeutic dose, minimum partially prophylactic and/or completely prophylactic dose, maximum and fully tolerated doses, and the therapeutic index. The salient points in the comparative data in the tables are brought out in the discussion portion of each chapter and an attempt is made to derive general conclusions and principles regarding chemical structure and biological activity.

Summary tables list compounds in order of their minimum effective therapeutic dose, therapeutic index, and prophylactic activity.

Appendixes list the more commonly employed salts of the compounds tested, the sources of the compounds, and a bibliography of publications by the authors and their colleagues dealing with compounds discussed in the monograph. The report is indexed by compound number, based on the numbers assigned by the Office of Scientific Research and Development, under which practically all antimalarial testing was carried on during World War II, and extended to include compounds received at the National Institutes of Health after the war. The index contains cross references to tables in which the compounds can be found, to publications in the bibliography, and to sources.

Public Health
MONOGRAPH 9

The accompanying summary covers the principal findings presented in in Public Health Monograph No. 9, published concurrently with this issue of *Public Health Reports*. The authors are members of the staffs of the Laboratory of Tropical Diseases, National Microbiological Institute, and the Laboratory of Chemistry, National Institute of Arthritis and Metabolic Diseases, National Institutes of Health of the Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents, United States Government Printing Office, Washington 25, D. C. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch of the Public Health Service. Copies will be found also in the libraries of professional schools and the major universities, and in selected public libraries.

Radiation Exposure in the United States

By DADE W. MOELLER, M.S., JAMES G. TERRILL, JR., C.E., M.B.,
and SAMUEL C. INGRAHAM, II, M.D., M.P.H.

THE HUMAN RACE has always been exposed to some ionizing radiation of cosmic origin and from natural sources in the environment and within the body. During a lifetime, a person who lives to be 70 years of age is exposed, on the average, to about 9 roentgens of radiation from these sources. Today, however, radiation from these sources comprises only a small portion of the total exposure received by man. Radiation-generating machines and radioactive materials, which are being employed in nearly all phases of the environment, constitute the principal sources of radiation.

Knowledge of the wide variety of sources and of the levels of radiation exposure is essential to the planning and conducting of a sound radiological public health program. Data available in the literature on the extent of radiation exposures in the United States are reviewed here to aid the many State and local health departments engaged in determining and evaluating radiation sources affecting public health in their areas. Neither the control of radiation exposure nor specific public health effects of the exposure are discussed in this paper.

Mr. Moeller, a sanitary engineer, is an environmental radiation specialist with the radiological health branch, Division of Engineering Resources, Bureau of State Services, Public Health Service. Mr. Terrill is acting chief of the branch and chairman of the Committee on Radiological Health of the Engineering Section, American Public Health Association. Dr. Ingraham is assistant chief of the branch.

Medical and Dental Uses of X-ray

In the United States today, more than 125,000 X-ray units are being used for diagnosis and therapy—approximately 50,000 by general practitioners, physician specialists, radiologists, and in hospitals and clinics (1); 65,000 by dentists; and 11,000 by doctors of osteopathy and doctors of chiropractic.

In the operation of these X-ray units, more than 215,000 medical-technical personnel are potentially exposed to radiation. These personnel include about 3,000 radiologists devoting full time to their specialty, 500 physicians devoting most of their time to radiology, 600 physicians who are second- and third-year residents in radiology, 31,000 general practitioners and specialists owning their own equipment (1), 67,000 dentists, 11,000 osteopaths and chiropractors, 40,000 X-ray technicians, and probably close to 40,000 dental technicians and assistants. This listing undoubtedly omits many nurses, clerks, attendants, and technicians who are exposed to radiation in a lesser degree.

Although many instances of excessive exposure of X-ray personnel are reported in the literature, few specific data are available regarding average exposure for these workers. In a 3-week survey of personnel in doctors' and dentists' offices and X-ray departments, it was found that about 3 percent of the exposures exceeded the present-day maximum permissible dose of 0.3 roentgen per week. However, 81.5 percent were less than 0.05 roentgen per week (2). In a 9-month survey of personnel in X-ray departments only, about 0.4 percent of the exposures exceeded 0.3 roentgen per week,

X-ray units in the healing arts

with 97 percent being less than 0.05 roentgen per week (2).

Exposures of X-ray personnel in Public Health Service hospitals range from 0 to 0.46 roentgen per 2-week period. An appreciable fraction of radiologists experience exposures averaging more than 0.1 roentgen per day. About 20 percent of the personnel operating photofluorographic equipment exceeded 0.3 roentgen per week prior to the start of a successful radiation control program.

Operators of dental X-ray machines receive approximately 0.1 roentgen of general body exposure per eight mouth examinations, each of which consists of ten 3-second exposures. This figure assumes careful operation of the unit. In conducting mass dental X-ray surveys, operators can easily receive the maximum permissible dose of radiation even with some rotation of operators. Persons in the immedi-

ate area of dental X-ray units can receive appreciable percentages of the maximum permissible dose.

In addition to the operators, a considerable portion of the general population is also exposed to radiations from X-ray machines. Of the 2,500,000 persons seen daily by physicians, a large number have some X-ray diagnostic procedure performed upon them by the physicians, and 82,000 are referred to radiologists. Approximately 25,000,000 X-ray examinations are given annually by radiologists (1). Data relative to radiation exposures resulting from these examinations are summarized below:

Type of examination	Average radiation dosage (roentgens)	Distribution (percent)
Radiographic.....	2.7	51.88
Photofluorographic.....	1.0	33.64
Fluoroscopic.....	65.0	14.48

Industrial X-ray installation

The radiation exposures range from approximately 1 roentgen for a photofluorographic examination to about 65 roentgens for an average fluoroscopic examination. Using the data in the above table and weighting each radiation dosage by its percentage distribution, an overall average radiation dose can be calculated. This average dose is 11 roentgens per examination.

X-ray treatments given annually by radiologists number more than 4,000,000 (1). These treatments are usually confined to a very small portion of the patient's body, and are usually administered at several sittings. The average total dosage per patient is about 5,000 to 7,000 roentgens.

Probably the largest single source of medical radiation exposure in the United States is the mass chest X-ray survey for tuberculosis. An estimated 15,000,000 persons were given chest X-rays in such surveys in 1950. Most of the X-rays given in the mass survey are the photofluorographic type, which results in about 1.0 roentgen exposure to the patient's chest per examination.

Some 84,000,000 films are used annually for dental X-ray examinations. In 1949, the 60 million persons (40 percent of the population) who visited their dentists were potentially exposed to radiation from this source. The average exposure to the patient per film is about 5 roentgens, most of the exposure being limited to the mouth of the patient.

X-ray in Industry

Industrial X-ray devices include primarily (a) radiographic and fluoroscopic units used for the determination of defects in castings, fabricated structures, and welds, and (b) fluo-

roscopic units used for the detection of foreign material in, for example, packaged foods. At present, there are approximately 800 industrial radiographic installations in the United States (8), and about 5,000 persons are potentially exposed to radiation in the use of the equipment. Industrial X-ray units, both radiographic and fluoroscopic, probably number about 2,000.

Exposure levels for personnel operating these machines depend upon the type of installation and the operating procedures used. Most permanent installations were designed and the personnel assignments planned so as to limit exposures to the levels recommended by the National Committee on Radiation Protection at the time the installation was built. However, the downward revision of the maximum permissible dose calls for a reevaluation of the older installations.

Fluoroscopy is also sometimes used for the scanning of personnel to detect pilfering. Exposures of 0.045 to 0.09 roentgen per inspection may be received by the "subject." The unit operator may receive 0.1 roentgen, largely limited to his head and shoulders, for each 50 persons inspected (4).

Other potential sources of X-ray exposure in industry are found in connection with the manufacture, testing, and operation of high-voltage electronic tubes. Personnel exposures may range as high as 2.5 roentgens per day.

Commercial Use of X-ray

The use of fluoroscopy in shoe-fitting results in radiation exposures to both operators of the fluoroscopes and the public. Mean exposures for the customer range from 7 to 14 roentgens per 20-second exposure. Although the radiation is intended only for the feet, dosages of 0.03 to 0.17 roentgen per 20-second exposure may be received by the pelvis. The number of exposures received by shoe customers is not known. In the operation of the approximately 10,000 fluoroscopes in the United States, 30,000 to 40,000 sales people are exposed to radiation.

X-ray in Research

With the development of atomic and nuclear physics, high-voltage X-ray machines have be-

come familiar features of research laboratories in universities and similar institutions. Few data are available as to the levels of exposure received by personnel in these radiation laboratories. Injuries have probably been held to a minimum by frequent turnover of personnel. However, in laboratories where cyclotrons, linear accelerators, and positive ion tubes, as well as high-voltage X-ray machines, are used, it is estimated that there is a frequency rate of "one palpable injury per 20 to 30 man-years of active employment in radiation work" (5).

Also in use for research purposes are about 1,500 X-ray diffraction units. Surveys of these units by the radiological health branch of the Public Health Service have recorded intensities of scattered radiation up to 1 roentgen per hour. Several cases of skin ulcers resulting from accidental overexposures in the use of these units have been reported.

Another X-ray unit found in many laboratories is the electron microscope. Approximately 500 are in use. Intensities of scattered radiation from these units may range up to 1.5 roentgens per hour.

Radioisotopes Distributed by AEC

More than 900 universities, hospitals, and research laboratories in 46 States have used or are using radioisotopes produced by the Atomic Energy Commission for medical, biological, industrial, agricultural, and scientific research, and medical diagnosis and treatment. During 1950 an average of 45 curies of radioactive isotopes were distributed per month. There are currently some 7,500 persons who are directly involved in the use of these materials. About 1 in 300 radioisotope users exceeds the present-day maximum permissible dose in a given week. Fifty to seventy-five percent receive less than 0.05 roentgen per week.

Patients to whom radioisotopes are administered internally may receive up to 10 or more roentgens whole-body exposure from diagnostic doses and 75 to 100 roentgens from therapeutic doses. Calculated dosages to single organs, such as the thyroid gland, range from 10,000 to 300,000 roentgens.

Radioisotopes are also used in medical therapy as external sources of radiation. Beta-ray

applicators are available for the treatment of certain eye conditions. Cobalt-60 is available in the form of large shielded concentrated sources for deep therapy and in the form of small needle sources for intracavitary and interstitial therapy.

Cobalt-60 is used industrially for radiography. About 80 sources are being used in the United States in industries such as railroading, steel production, boiler-making, automobile manufacture, ceramics production, pressure vessel manufacture, and the making of castings. The intensity of radiation from 1 curie of unshielded cobalt-60 at 1-foot distance is 14.4 roentgens per hour. The quantities used in industry range from 100 or 200 millicuries up to as high perhaps as 1 curie.

Thickness gauges using radioisotopes are becoming more and more popular in industry. More than 50 such gauges using strontium-90 and some 20 using other radioisotopes are presently in use in the United States. Surveys have shown that the external radiation to which personnel working around these units are exposed is well below the maximum permissible dose. Strontium-90 is also used to activate phosphors for use in luminous markers, which are hermetically sealed to prevent escape of the radioactive material.

These and other radioisotopes are being widely used in a variety of industrial research problems.

Within the next few years, industrial uses of fission products are expected to become more widespread. Through 1950, however, only about 4 curies had been distributed by the Atomic Energy Commission.

Wastes from the use of radioisotopes in industry, the medical profession, and research laboratories could cause radiation exposure to persons outside the installations using the radioisotopes. Safe disposition procedures are well covered in official publications.

Radium

The radiation from 1 curie of radium, in equilibrium with its decay products and enclosed in 0.5 mm. of platinum will produce a gamma-ray exposure of about 9.0 roentgens per hour at a distance of 1 foot.

INCREASE OF RADIATION

Many individuals are potentially exposed to radiation in the medical use of radium. Patients receive radiation dosages comparable to those given in X-ray treatment. Nurses and other persons attending the patient are also exposed during the course of treatment. Technicians and therapists often receive high exposures since radium can seldom be applied accurately with remote handling devices. Local exposure to their hands often exceeds 1 roentgen per day. In the preparation and handling of radon applicators, these personnel may receive additional radiation exposures.

During World War II, radium was used extensively in the United States for industrial radiography, largely because X-ray units were difficult to obtain. As much as 100 grams were in use. In 1948, the amount had declined to 50 grams (6). At present, many of the radium radiographic installations have been replaced by X-ray machines and cobalt-60.

Radium sources are commercially available in 25-, 50-, 100-, 200-, 300-, and 500-milligram units. The 100- and 200-milligram units are most commonly used. Average exposures received by industrial personnel handling radium are not known.

Another industrial use of radium is in self-luminous paint. During World War II, several thousand workers were using this paint, and several hundred grams of radium were utilized. After the war, the number of workers decreased until in 1948 there were only about 300 (6). Although each worker handles only a small quantity of radium, the hazards are great since the radium is not sealed in a container and can therefore be ingested or inhaled.

Under present conditions, it is recommended (National Bureau of Standards Handbook 47) that the amount of radium-226 fixed in the body should not exceed 0.1 microgram. Fatalities have been known to occur when the amount was approximately 1 microgram. Under the best working conditions existing in 1943 in the radium-dial-painting industry, 15 percent of the workers accumulated more than the maximum permissible amount (7). In a recently reported survey at an instrument shop, a degree of radium contamination greatly in excess of the maximum permissible concentration was found.

It is generally accepted that the maximum permissible concentration for radon in the air is 10 micromicrocuries per liter (5). When workroom ventilation requirements are met, the radon concentration in the workroom air does not exceed 30 percent of the maximum permissible concentration. However, ventilation requirements are not always met, especially in storage and packing rooms and offices.

The normal gamma-radiation exposure received by dial-painting workers appears to be about 0.02 roentgen per day (5). Exposures to radiation may also occur in the use of finished products containing a luminous compound. A watch may have approximately 1 microgram of radium on it. Some clocks and aircraft instruments contain from 10 to 100 micrograms of radium. The level of exposure at the instrument panel in airplanes so equipped may be 0.01 roentgen per hour, and at the pilot's body position from 0.0002 to 0.001 roentgen per hour.

An important factor to be considered in determining radiation exposure in the United States is that radium and many other naturally radioactive materials may be purchased on the open market. No formal application or special facilities are required in order to obtain these materials.

Numerous instances of radium being lost have been reported, all constituting danger of unsuspected radiation exposure. Taft (8) has reported on 107 losses, with 59 complete recoveries, 11 partial recoveries, 36 total losses, and 1 not recorded.

Static Eliminators

Static eliminators containing radioactive sources are widely used in textile and paper trades, printing and photographic processing industries, and by telephone and telegraph companies. They are also used with analytical balances and microtomes.

One type consists of a bar containing a strip of metal impregnated with radium. A thin layer of gold and nickel is plated over the radium metal strip to protect the radium and act as a seal. The main hazards from this type result from exposure to beta and gamma radiation (alpha constitutes little external hazard) and radon gas.

Exposure levels in the working areas near these units are generally about 0.005 roentgen per hour but may range up to 0.085 roentgen per hour. Unless care is exercised and the necessary shields used, maintenance men and other workers whose duties require them to be close to such units frequently can be exposed to radiation levels as high as 1 roentgen per hour.

The radon hazard is small if the units are given proper care and used in ventilated areas. However, if the seal is broken, a radon hazard may result. Several surveys have pointed out that improper storage and handling of static eliminators is common.

A second type of static eliminator contains polonium as the radioactive source. This unit constitutes little external radiation hazard since the alpha particles from polonium travel only a short distance in air. The hazards associated with its use result from ingesting, absorbing, or inhaling polonium liberated through breaking or flaking of the gold seal.

Small polonium bars are also mounted on brushes as static charge eliminators for phonograph records and photographic films.

A point about polonium that must be given careful consideration in certain applications is that polonium volatilizes at lower temperatures than radium.

Shipping of Radioactive Materials

Radiation exposures can occur during the handling and shipping of radioactive materials. Under the current regulations governing the shipment of these materials by air, the maximum exposure which an airplane crew member or passenger could receive would be 0.012 roentgen per hour. The maximum exposure for pilots (flying 85 hours per month) would therefore be 1.02 roentgens per month (9).

Nuclear Reactors

Radiation exposures associated with the operation of nuclear reactors include those from the reactor itself, from its ventilation and cooling effluents, and from its fission products.

Data on the "water boiler" type reactor being built at the North Carolina State College serves as a tentative guide in establishing the

Enriched-uranium, graphite-moderated reactor

importance of such installations as sources of radiation exposure (10).

A maximum of some 10^5 curies of activity will be present in the fuel solution of this reactor. Heavy shielding will be required to limit all radiation exposure from the reactor and its accessories to a safe level.

At maximum operating level, 10 kilowatts, the reactor will require 3 gallons of water per minute for cooling. Upon leaving the reactor, the water will contain some 1,000 disintegrations per second per cubic centimeter. Assuming no shielding and no internal absorption of radiation by the water, 10 gallons of freshly irradiated water would produce a radiation dosage rate of approximately 0.08 roentgen per 8 hours at a distance of 5 feet. After 1 hour, the dosage rate would drop to about 0.0008 roentgen per 8 hours at a distance of 5 feet. Tanks for collecting and retaining this waste water for 10 hours will be provided.

Some 40 liters per hour of waste gases will be produced at 5 kilowatts normal operating level. The activity of these gases will amount initially to about 7,000 curies per kilowatt minute. After 4 hours, however, this 7,000 curies will have decayed to 0.15 curie.

Solid as well as other liquid and gaseous wastes will result if laboratory or experimental

programs are conducted in conjunction with operation of the reactor, or if the used nuclear fuels are reprocessed.

A second type of nuclear reactor, an enriched-uranium, graphite-moderated reactor, is being built for industrial research. It will be operated at a maximum power level of 200 kilowatts. Shielding, weighing a total of 450 tons, will be provided by 6 inches of steel and about 3 feet of "heavy" concrete. Data as to the wastes from operation of this reactor and the possible resulting radiation exposures have not been released.

Undoubtedly, other reactors will soon be built at other colleges and universities and in industry. At least five major universities have expressed interest in following the steps of North Carolina State College.

Particle Accelerators

In 1941, there were only some 16 cyclotron laboratories in the United States. Today, however, more than 100 particle accelerator units, including cyclotrons, synchrotrons, van de Graaff generators, and betatrons, are in use.

Exact determination of the type and intensity of radiation encountered around particle accelerators is often difficult and sometimes impossible because of the mixture of radiations present. Beta radiation originates from the various accelerators, but the possibility of direct exposure is slight. Neutrons probably constitute one of the main hazards, as they are produced in profusion in the operation of cyclotrons and synchrotrons.

Impaired vision of several nuclear physicists as a result of work with cyclotrons was reported

recently. The general injury rate for laboratory radiation workers was discussed above under X-ray in Research.

AEC Activities

Activities sponsored by the Atomic Energy Commission which result in radiation exposure include uranium mining and milling, nuclear reactor operations, and testing of weapons.

Uranium mining and milling in this country is carried on primarily in the region of the Colorado Plateau. Some 2,000 miners and millers are engaged in this work. The mining and processing of the ores and metals yields dusts and fumes which are sources of radioactive air pollutants. Radon gas is also a hazard. The Public Health Service and several State health agencies, which are active in studies of the specific hazards in this industry, have reported finding radon exposures above the maximum permissible concentration in several of the mines. In these instances, control measures, particularly ventilation, are being applied as rapidly as possible. Detailed physical examinations of over 1,100 workers have revealed no evidence of health damage from radioactivity.

Atomic Energy Commission installations conducting nuclear reactor operations are located in many areas of the United States. The radius of the potential health hazards of these operations may be increased by the discharge of radioactive liquid and gaseous wastes. For example, the installation at Oak Ridge, Tenn., discharges up to 5 curies per day of liquid wastes to the White Oak Creek. The potential risks are by no means always confined to those directly associated with such activities. For these reasons, an effective radiation control program has been an integral part of atomic energy operations since their inception.

In 1951, 12 bombs were detonated at the AEC Proving Ground in Nevada. The activity 1 hour after detonation of a nominal atomic bomb is approximately 10^9 curies. One week later, about 10^7 curies remain. Fortunately the majority of this radiation probably remains in the upper atmosphere, but some of it is widely distributed causing a temporary average increase in radioactivity throughout the United States.

The 184-inch Berkeley synchrocyclotron

Accidents

Numerous instances of radiation injury from accidents have been recorded in the literature. Moreover, it is believed that these represent only a small fraction of the accidents which occur. Any radiation exposure resulting from accidents would be in addition to the exposures discussed here. Obviously, the potential amount of exposure and the probable severity of injury incurred in an accident would vary with the amount of radiation involved.

Summary and Conclusions

A review of the literature reveals that the average annual radiation exposure from medical diagnostic procedures is about 2 roentgens per person. This exposure is received by a large portion of the population. Other medical sources of exposure are dental X-rays and medical radiation treatments.

Many segments of the population receive additional exposures as a result of contact with radioactive materials and radiation-generating units in commerce, industry, and research.

From the data presented, it is not possible to reach definitive conclusions as to the magnitude of the radiological health problem or as to the relative importance to public health of the several sources of ionizing radiation. It is hoped, however, that publication of this paper will encourage further studies which will lead to more conclusive data.

This review, meanwhile, indicates that large numbers of the population are currently exposed to radiation appreciably in excess of natural background. Such exposure often approaches doses recommended as the maximum permissible for radiation workers. The sources of these exposures vary from community to community, and their relative health importance is continually changing.

A tremendous national effort is being made by military and civilian agencies to expand the production and use of radioactive materials. It is expected that the near future will bring nuclear reactors for power production, research, and transportation into widespread use. Many radiological health workers believe that as this technological development occurs pro-

tection from radiation must become a major concern of public health programs. The time to organize and train to meet the radiological health responsibility of the future is at hand. The ability of health workers to cope with public health problems arising from the increasing hazard of ionizing radiation will be more readily developed if they learn to search out and to deal with the radiological health problems of today.

Chemical Labeling Committee Reactivated

THE INTRODUCTION within recent years of a multitude of new chemicals and the increasing commercial application of chemical products have intensified the need for proper precautionary labeling. The use of adequate warning designations on containers of chemical products is essential in protecting the health of not only those who handle these materials in their various repackaging and processing stages but also of the ultimate consumers.

To reappraise current needs and to take new steps to meet today's problems, the Public Health Service is reactivating the work of the Chemical Products Agreements Committee, which had functioned prior to 1950. The new committee, to be known as the Chemical Products Labeling Committee, will serve in an advisory capacity to the Labels and Precautionary Information Committee of the Manufacturing Chemists' Association and to other agencies, such as State health and labor departments. The Public Health Service will provide a focal point in the Federal Security Agency for obtaining expert opinion on the need for labeling as well as for developing base lines for uniform labeling practices.

In recent years, practically every State health department and many labor departments have become interested in the labeling of toxic materials, and the resultant development of varying labeling requirements throughout the country has made it difficult for industry to cooperate.

In the interest of promoting uniform labeling, an effort will be made by the Chemical Products Labeling Committee to unite the activities of the various groups interested in this problem, to encourage better labeling practices throughout industry, and to assist in the development of improved labels.

The forerunner of this committee, in cooperation with the Manufacturing Chemists' Association, had been concerned with the develop-

ment and administration of specific agreements between the Surgeon General and certain chemical manufacturers, covering warning designations to be used on containers. Drawn up in the early 1930's, these agreements with manufacturers of methanol, carbon tetrachloride and other chlorinated hydrocarbons, carbon disulfide, aniline, benzene, and chlorinated naphthalenes, diphenyls, and diphenyl oxides were self-limiting because they were designed for specific conditions. These agreements have now been discontinued by the Public Health Service as part of its efforts to foster broader labeling practices better adapted to present conditions.

The products specified in the agreements that have now been abrogated, as well as all other potentially hazardous chemicals, are covered by a label pattern developed by the Labels and Precautionary Information Committee of the Manufacturing Chemists' Association, with the concurrence of the Public Health Service. Such a pattern is believed to afford a more feasible approach to the problem presented by the tremendous expansion of the chemical industry.

Surgeon General Leonard A. Scheele, commending the work of the Labels and Precautionary Information Committee, indicated that the Public Health Service endorses the principles of labeling as set forth in part I of Manual L-1, Warning Labels, published by the Manufacturing Chemists' Association. He stressed that the identification of potentially hazardous materials through proper and uniform labels is vital to the public health.

This labeling program has been developed for bulk packages of chemicals intended for commercial use and in no way affects the provisions of the Federal Caustic Poison Act, which applies to some caustic and corrosive chemicals intended for household use, or of the Federal Food, Drug, and Cosmetic Act, which requires adequate warnings on the labels of all drugs.

Members appointed by the Surgeon General to the Chemical Products Labeling Committee represent a cross section of Public Health Service activities related to this problem. Joseph E. Flanagan, Jr., assistant chief, Division of Occupational Health, will serve as chairman of the committee; members will be Dr. Samuel W. Simmons, chief of the technical development branch, Communicable Disease Center; Frederick S. Kent, chief of the home

accident prevention unit, Division of Sanitation; Dr. Donald J. Birmingham, chief of the clinical investigations section and of the dermatology unit, Division of Occupational Health; Dr. Herbert E. Stokinger, chief toxicologist, Division of Occupational Health. The Manufacturing Chemists' Association has appointed as a representative on this committee the chairman of its Labels and Precautionary Information Committee.

Diphtheria in the United States

The incidence of diphtheria in the United States has shown a steady decline during the past few decades. From a 3-year average rate of 60.3 cases per 100,000 population for 1929-31, the rate dropped to an average of 3.9 for the period of 1949-51. It is estimated by the National Office of Vital Statistics that 3,200 cases of diphtheria will be reported in 1952, which would be a morbidity rate of about 2 cases per 100,000 population for the year.

During the last 2 decades decreases have occurred in diphtheria incidence rates for each of the geographic divisions, but these decreases, as shown in the chart, have

not been of the same magnitude in each division. The highest rate (82.8) in 1929-31 was in the South Atlantic division. In 1949-51 the high incidence has shifted farther south and the rate of 8.9 in the East South Central division was the highest. On the basis of data available in November 1952, it is estimated that the rates in 1952 in the various geographic regions will be approximately as follows: New England 0.5 cases per 100,000 population, Middle Atlantic 0.9, East North Central 0.7, West North Central 1.4, South Atlantic 4.3, East South Central 5.6, West South Central 4.1, Mountain 1.6, and

Pacific 1.3. In each instance this represents a substantial decrease as compared with average rates for the 1949-51 period.

Comparison of the percentage of the total cases occurring in the various areas also shows the shift in incidence from northern to southern States. For the period 1929-31, 34 percent of the cases in the United States were reported in the three southern divisions; Middle Atlantic, East South Central, and West South Central. During 1949-51, 64 percent occurred in these areas and in 1952 the proportion is still greater, namely 68 percent.

DIPHTHERIA BY GEOGRAPHIC DIVISIONS

(AVERAGE MORBIDITY RATES PER 100,000 POPULATION)

Estimated population July 1, 1930, 1940, and 1950.

Deaths

per 1,000 population

Births

per 1,000 population

United States Vital Statistics, 1951-1952

A new high for births and a continuing low level for deaths appear very likely for 1952 (table 1). Thus the natural increase in the population of the United States—that is, births minus deaths—should be greater than for any previous year. Marriages in 1952 continued to drop from the all-time high reached in 1946. On the basis of data from 19 States, divorces, which have also dropped off since their 1946 peak, appear to be rising slightly in 1952. These statements are based on provisional figures for States shown in the *Monthly Vital Statistics Report* for January–September 1952. Each month the figures are sent by State and local officials to the National Office of Vital Statistics.

Deaths

Mortality statistics for the United States show that for the last 4 years, 1948–51, less than 10 people out of every 1,000 died during the year. For the first 9 months of 1952 the death rate was 9.6 deaths per 1,000 population, indicating that 1952 is likely to rank along with 1950 in having the lowest death rate on record.

For the past 15 years, 1937–51, the infant mortality rate (deaths under 1 year of age per

1,000 live births adjusted for changing numbers of births) for each year has been lower than that for the preceding year. For the period January–September 1952, the infant mortality rate was 28.3, so that 1952 may prove to be no exception to this trend of ever lower annual rates.

The summer of 1952 was noteworthy for long spells of record-breaking hot days in many parts of the country. That the heat wave had some effect on mortality is evident in two of the accompanying charts. Generally, in its seasonal variation the death rate decreases from May to June. Last year the death rate swung upward from 9.4 deaths per 1,000 population for May to 9.8 for June, the highest rate for June since 1944. The infant mortality rate rose from 28.2 infant deaths per 1,000 live births for May to 30.2 for June, contrary to its usual downward seasonal swing. Unusual increases were noted in the death rates for diseases of the cardiovascular system, for accidents, for homicide, and for some gastrointestinal diseases.

Table 2 gives the estimated death rates for selected causes in the United States during the first 9 months of 1951 and of 1952. The relative timeliness of information on causes of death is made possible through the cooperation of the States in sampling their death records monthly. The State vital statistics offices send to the national office every tenth death certificate, which

Prepared by the National Office of Vital Statistics, Public Health Service.

Infant mortality

per 1,000 live births

is processed immediately. However, this early information is less accurate than the complete data that will be available when all the death certificates are received. A discussion of the amount of error to be expected as a result of sampling variation is presented in the *Monthly Vital Statistics Report*.

Births

In 1951 and the first 9 months of 1952 the number of births exceeded records set in 1947. For January–September it is estimated that 2,856,000 births were registered in 1952 as compared with 2,811,000 in 1951 (table 1). The number recorded during all of 1951 (3,758,000) was in turn almost 2 percent above the 1947 figure of 3,699,940 (final). In the years between these high points, the annual number of registered births held consistently at 3½ million.

Marriage licenses

per 1,000 population

The total number of births is slightly larger than the number registered because of the failure to register some births. It is estimated that 3,833,000 children were born in 1951 as compared with 3,817,000 in 1947.

The crude birth rate serves to indicate what proportion births bear to the current population of all ages. In a period of rapidly increasing population, as at present, this proportion may decline despite a rise in the number of births. Thus, the crude birth rate based on registered births was 24.5 per 1,000 population in 1951 and 25.8 in 1947. Between 1950 and 1951, a period in which the number of births rose sharply, the rate also increased (from 23.5 to 24.5). The slightly higher number of births in the first 9 months of 1952 as compared with 1951 caused no change in the birth rate, which was 24.6 for both periods.

Table 1. Vital statistics: United States, January–September, 1951 and 1952

	Number			Rate		
	1952	1951	Percent change	1952	1951	Percent change
Live births:						
Registered.....	2,856,000	2,811,000	+1.6	24.6	24.6	0
Corrected for under-registration.....	2,905,000	2,867,000	+1.3	25.0	25.1	-0.4
Marriage licenses.....	1,161,840	1,223,951	-5.1	10.0	10.7	-6.5
Deaths.....	1,114,000	1,106,000	+0.7	9.6	9.7	-1.0
Infant deaths.....	80,500	79,400	+1.4	28.3	28.6	-1.0

NOTE: Deaths exclusive of fetal deaths and of deaths among armed forces overseas. Birth, death, and infant death data estimated. Birth, death, and marriage license rates per 1,000 population excluding armed forces overseas; infant mortality rates per 1,000 live births and adjusted for changing numbers of births. All rates on an annual basis. Population estimates prepared by the Bureau of the Census.

The recent upsurge in births began early in 1951 with peak increases over 1950 occurring in the months March through June. In the latter half of 1951, the birth rate each month exceeded that for the corresponding month of 1950, but by a smaller margin. The chart com-

Table 2. Estimated death rates for selected causes of death: United States, January-September, 1951 and 1952

[Exclusive of fetal deaths and of deaths among armed forces overseas; rates on an annual basis per 100,000 estimated population, excluding armed forces overseas]

Cause of death	Death rate, January- September	
	1952	1951
All causes.....	958.9	966.6
Tuberculosis, all forms.....	17.3	20.3
Syphilis and its sequelae.....	3.7	4.6
Dysentery, all forms.....	.6	.7
Diphtheria.....	.1	.2
Whooping cough.....	.3	.7
Meningococcal infections.....	1.0	.7
Acute poliomyelitis.....	1.9	.7
Measles.....	.4	.7
All other infective and parasitic diseases.....	3.3	2.9
Malignant neoplasms, etc. (principally cancer).....	142.7	141.6
Diabetes mellitus.....	16.2	16.4
Major cardiovascular-renal diseases.....	507.5	511.7
Diseases of cardiovascular system.....	493.8	496.3
Vascular lesions of central nervous system.....	108.5	104.6
Rheumatic fever.....	1.0	1.1
Diseases of heart.....	350.6	355.5
Hypertension without mention of heart and general arteriosclerosis.....	28.3	30.2
Other diseases of circulatory system.....	5.4	4.8
Chronic nephritis, etc.....	13.7	15.4
Influenza and pneumonia, etc.....	31.3	32.7
Ulcer of stomach and duodenum.....	5.6	5.4
Gastritis, duodenitis, enteritis, etc.....	5.4	5.1
Cirrhosis of liver.....	9.8	10.0
Acute nephritis, etc.....	1.8	2.1
Complications of pregnancy, etc.....	1.6	1.8
Congenital malformations.....	12.1	11.8
Senility, etc., and ill-defined conditions.....	15.2	16.7
Motor-vehicle accidents.....	22.2	21.1
All other accidents.....	38.9	38.9
Suicide.....	10.0	10.5
Homicide.....	4.8	4.5
All other causes.....	105.0	104.5

NOTE: Figures are based on a 10-percent sample of death certificates. The sampling error varies with the size of the death rate. For example, the estimate for diseases of heart is subject to an error of 0.5 percent, and for syphilis, 4 percent. Diphtheria, with a rate of only 0.2, is subject to an error of 22 percent.

paring monthly rates for 1951 and 1952 through September indicates that the main increases in 1952 occurred in July through September.

Part of the over-all increase in births in 1951 and 1952 was undoubtedly due to greater numbers of first-order births resulting from the sharp rise in marriages soon after the outbreak of hostilities in Korea. However, it is likely that increased numbers of higher-order births in these years also contributed to the gain.

Marriages

Monthly marriage license rates for the United States in 1951 and in 1952 through September (fourth chart) reveal a fairly similar seasonal pattern. Fewer marriage licenses are issued during the winter months than in the spring and summer, and June is the most popular month for obtaining marriage licenses.

In the past, marriage licenses have been responsive to such factors as the demobilization following the last war, the outbreak of hostilities in Korea, and the varying dates of Easter. The low birth rates during the business depression of the early 1930's, with the consequent reduction in numbers of young persons reaching marrying age during the current period, are now adversely affecting the number of marriages.

Because marriages by month on a current basis are not obtainable for the United States, the National Office of Vital Statistics publishes data on marriage licenses, rather than marriages, for most States. On an annual basis, the number of marriages is 1 to 3 percent less than the number of marriage licenses. Monthly figures on marriage licenses start with data for 1944, and annual figures on marriages go back to 1867.

Figures on marriage licenses for city areas that have populations of 100,000 or more are available by month starting with 1939.

Divorces

Current monthly figures on divorces for 19 States are published in the *Monthly Vital Statistics Report*. A somewhat larger group of States will be represented in the 1953 issues of this report. Annual estimates on divorces in the United States are available from 1867 through 1951.

Birth Statistics in Maternal and Child Health Programs

By WILLIAM HAENSZEL, M.A.

MANY convincing reasons can be advanced for processing all data from birth certificates as a single integrated operation. The data cannot, for example, be segregated into two watertight compartments—legal and medical. Such items as race, place of delivery, and previous child-bearing history of the mother are all part of the legal certificate, which is handled by the bureau of vital statistics, but they must also be taken into account in tabulating and interpreting the medical data, which in some places is handled by maternal and child health personnel. Processing a single punch card eliminates some duplication of work and simplifies scheduling of coding, punching, and tabulating procedures. Furthermore, the bureau of vital statistics is best equipped to conduct follow-up inquiries to complete information and routinely match infant death certificates with birth records. Desired birth tabulations can be furnished to maternal and child health administrators.

This paper deals primarily with problems of collection and analysis of material usually found on the medical supplement of the birth certificate, including data on fetal and neonatal

deaths. Recapitulating and summarizing developments in this field since 1940 has been greatly simplified by activities undertaken by the Public Health Conference on Records and Statistics, the Association of Maternal and Child Health and Crippled Children Directors, the National Office of Vital Statistics, and the Children's Bureau. Where opinion has crystallized, these organizations have made recommendations on definitions and tabulations for birth weight and related characteristics (1, 2).

Definitions and Grouping of Items

The need for and importance of standard definitions and procedures cannot be overemphasized. Comparisons—between hospitals and local areas within the State as well as on the interstate and international levels—are the heart of this enterprise. Each maternal and child health administrator has a stake in having tabulations for his jurisdiction which can be compared with experience elsewhere.

For death certificate terminology, there is the standard medical certification form and the elaborate machinery of the International Statistical Classification of Diseases, Injuries, and Causes of Death, and ancillary instruction manuals. For birth certificates, the phrasing and presentation of certain medical supplement items is still under study. The International List is not completely suitable for classifying complications of pregnancy and labor or operative procedures.

Lack of standard groupings for birth weights has been a deterrent to interarea comparisons of the proportion of immature births and

Mr. Haenszel is chief of the biometrics section, National Cancer Institute, National Institutes of Health, Public Health Service. This paper was presented at the 2d Conference on Public Health Statistics, School of Public Health of the University of Michigan, Ann Arbor, on June 17, when Mr. Haenszel was director of the bureau of vital statistics, Connecticut Department of Health, Hartford.

weight-specific mortality rates. The distribution curves according to birth weight for live births and neonatal deaths exhibit steep gradients, at the smaller weights particularly. Differences of only a few ounces in class limits render the data virtually incomparable.

A detailed grouping of birth weights in intervals of 250 grams, with corresponding avoirdupois weights, has been published (1). The intervals have been so arranged that one division point, 2,500 grams (5½ pounds), coincides with the weight criterion for an immature birth in the International Statistical Classification.

The importance of hospitals following standard procedures for recording birth weight is obvious (1). They should report in the units of measurement appearing on their scales (metric or avoirdupois) and not attempt to convert birth weights. Failure to report birth weight on the birth certificate for even a small proportion of births can distort data on incidence of immaturity and mortality in low weight groups. The residual group of unweighed babies will consist almost entirely of immature infants, because of the tendency to leave very small babies unweighed, and can be sizeable in relation to the number of babies actually reported in the smaller weight groups. Routine checks should be maintained on the completeness of birth weight reporting for individual hospitals.

Length of pregnancy is used principally for the adjustment and distribution of unknown or not stated birth weights. Improvement in reporting on this item will eventually make possible the joint use of birth weight and gestational age data for indicating maturity of the newborn child.

Tabulations for individual hospitals should refer to the hospital where delivery occurred, unless clearly specified otherwise. This is important in areas maintaining special premature nursery facilities, to which babies are transferred from other hospitals. Separate tabulations will usually be maintained for "transferred babies."

Pregnancy and Labor

The International Statistical Classification cannot be considered an entirely suitable frame-

work for classifying complications of pregnancy and labor. To date classifications have been constructed from terms actually reported on the birth certificate. Complications fall into three major groups—labor, pregnancy, and nonpuerperal. It is not difficult to develop a list of titles within each of these groups. Trouble arises when specific terms are collected under each title. Such categories as "dystocia" or "disproportion of fetus" can cover a wide variety of conditions. Differences in incidence and mortality for certain complications can often be traced to noncomparability in conditions covered. In the absence of a standard classification system, it is of great importance that the kinds of complications under each title be clearly specified in publications (preferably in an appended glossary of inclusions).

An investigation of hospital records for a birth certificate sample in upstate New York revealed extensive under-reporting of complications (3). Reporting was more complete for deliveries involving fetal or neonatal death, or cesarean sections. Under-reporting could be confirmed anywhere by tabulating the proportion of certificates with reported complications by hospital. In Connecticut (1948) this proportion ranged from 3.3 to 26.3 percent for individual hospitals (4); reporting was better in the larger hospitals with well-organized obstetrical departments.

A check-list format for the medical supplement has been recently introduced in New York State and, according to a preliminary study, increased the incidence of total complications reported from 14.4 to 17.3 per 100 births (5). Anemia, premature separation of placenta, postpartum hemorrhage, breech and other malpresentations, heart disease, and syphilis were among the complications for which better reporting was noticeable. The design of the medical supplement should call attention to reporting of operative indications as complications or physicians may omit reporting complications obviated by resort to surgery (4).

Comparison of unpublished data collected by the Connecticut and New York State Departments of Health has revealed close correspondence in rates for certain complications for which there was substantive agreement in conditions covered. The two areas resemble each other

closely in many vital statistics indexes, and these comparisons enhance the confidence to be placed in the stability of the data. They indicate that the birth registration system can deliver descriptive results, even though subject to some distorting biases.

The code for delivery procedures in the International Statistical Classification needs some modification. No serious objection can be raised to the grouping of mid and high forceps, in view of their infrequency and the difficulty of distinguishing between them from birth certificate reports. However, the combination of breech extraction and of version and extraction under "manipulation without instruments" seems unwise. The two procedures have different characteristics when analyzed with respect to complications and mortality.

Connecticut data have demonstrated marked disparity between hospitals in the proportion of low-forceps deliveries, which could be traced to disagreement as to whether terminal or prophylactic forceps constituted an operative procedure and were to be so reported on the birth certificate (4). Current Connecticut practice has been to code prophylactic forceps as low forceps. There is no pressing need to distinguish between low-forceps and spontaneous deliveries. In many areas, mortality rates (both fetal and neonatal) have been reported without exception as lower for low-forceps deliveries. This held true even when the rates were adjusted in Connecticut to take account of the smaller birth weights among babies delivered spontaneously (4).

The check-list approach, discussed for complications, could readily be extended to cover delivery procedures.

Malformations and Birth Injuries

The Sixth International List provides a suitable scheme for classifying congenital malformations. The classification for birth injuries appears unduly condensed, segregating only intracranial and spinal injuries from other birth injuries. Separate categories for fractures, facial paralysis, and brachial plexus injuries could be provided.

Congenital malformations and birth injuries are not always apparent when the birth certificate is made out. Consequently, reporting on

the medical supplement must be regarded as incomplete. The degree of under-reporting can be approximated by comparing neonatal death certificates mentioning malformations or birth injuries with the corresponding birth certificate. Reporting of birth injuries is definitely poorer than for congenital malformations, only one-third of the birth injuries having been reported, according to the New York State data (6).

Neonatal deaths

A neonatal death is defined as one occurring less than 28 days subsequent to birth. The following groupings of ages of death (1) should suffice for most purposes: under 1 hour; 1 to 23 hours; single days to the end of the first week; 7 to 13 days; 14 to 20 days; 21 to 27 days.

Causes of death may be grouped for tabular presentation. Reference 2 gives a list of 45 selected causes.

Handling Neonatal Death Data

Three specialized procedures necessary for the handling of birth and neonatal death data deserve comment.

1. Matching birth and death records is without doubt the most important single step to be taken in the development of adequate birth statistics. Provisions for matching should always include neonatal deaths and, if possible, deaths under one year of age.

2. Combining data from matching birth and death records on a single punch card is a prerequisite for the efficient handling of neonatal death tabulations. At least the following information should be available (1):

From the birth certificate: Certificate number; place of birth, including identity of hospital; place of residence; attendant; sex; plurality; month and year of birth; race; age of mother; order of birth; birth weight; length of pregnancy; and any other medical and health items that are usually punched.

From the death certificate: Certificate number; age at death; cause of death; place of death.

3. Adjustments to take account of the "not stated" birth weights are necessary. Reports of birth weight are more likely to be omitted for grossly underweight babies, including those

Table 1. Weight-specific neonatal death rates per 100 live births, New York City, 1949

Birth weight		White		Nonwhite	
		For known birth weights	Adjusted for unreported birth weights	For known birth weights	Adjusted for unreported birth weights
Total-----		1.5	1.8	2.2	2.8
<i>Grams</i>	<i>Pounds</i>				
Under 2,500-----	5 pounds 8 ounces or less-----	11.7	14.1	11.2	14.4
2,500 and over-----	Over 5 pounds 8 ounces-----	.6	.7	.9	1.0
Under 1,000-----	2 pounds 3 ounces or less-----	93.4	97.4	82.4	88.5
1,000 to 1,499-----	2 pounds 4 ounces to 3 pounds 4 ounces-----	43.3	47.0	39.0	40.7
1,500 to 1,999-----	3 pounds 5 ounces to 4 pounds 6 ounces-----	14.6	16.9	12.5	14.8
2,000 to 2,499-----	4 pounds 7 ounces to 5 pounds 8 ounces-----	3.1	3.5	3.0	3.6
2,500 to 2,999-----	5 pounds 9 ounces to 6 pounds 9 ounces-----	.9	1.0	1.1	1.3
3,000 to 3,499-----	6 pounds 10 ounces to 7 pounds 11 ounces-----	.5	.6	.8	.8
3,500 to 3,999-----	7 pounds 12 ounces to 8 pounds 13 ounces-----	.5	.5	1.0	1.0

4,500 to 4,999-----	9 pounds 15 ounces to 11 pounds-----	1.2	1.4	1.0	1.0
5,000 and over-----	11 pounds 1 ounce or more-----	4.5	6.2	0	0

NOTE.—Adapted from a table published by the Bureau of Records and Statistics, New York City Department of Health. The class intervals in grams are not precisely those recommended by reference 2. The avoidupois limits have been inserted to illustrate presentation format and may not represent exactly the weight groupings used.

born dead or with poor prospects for survival. Mortality rates, based only on known birth weights, understate seriously the true rates. The size of the correction in mortality will usually be greater for fetal deaths than for neonatal deaths. Allocation of unknown birth weights can be handled through a number of procedures now in effect (2).

Table 1 illustrates the effect of adjustment on weight-specific neonatal mortality rates. The correction is greatest for the under 1,000 grams group, becomes negligible in the 2,500- to 4,500-gram range, and then reappears at higher weights.

Tabulation of Data

Tabulations of medical supplement data have a wider audience than maternal and child health administrators. The needs of medical society committees, hospital superintendents and staffs, and of interested physicians must also be kept in mind.

Reference 2 outlines suggested tabulations for birth weight and related characteristics. Reduced to skeleton form, the suggested tabulations are:

1. Live births (and neonatal deaths) classi-

fied by birth weight, race, and county of residence (with subtabulations for cities of over 50,000 population).

2. Live births (and neonatal deaths), classified by birth weight and individual hospitals (also group hospitals according to size).

3. Single live births (and corresponding neonatal deaths), classified by birth weight, race, and person in attendance.

4. Single live births (and corresponding neonatal deaths), classified by birth weight, race, and sex; neonatal deaths further subdivided by age at death and by cause of death.

5. Plural live births (and corresponding neonatal deaths), classified by birth weight, race, and sex; neonatal deaths further subdivided by age at death and by cause of death.

6. Live births (and neonatal deaths), classified by birth weight, race, period of gestation.

Note: This report does not cover such topics as complications of pregnancy and labor, operative procedure, birth injuries, or congenital malformation.

The cross-tabulation "Birth weight by area of residence" may throw light on possible relationships between environmental factors and incidence of immaturity. It will delineate

the geographical pattern for incidence of immaturity and help determine those areas needing added special facilities for care of immature babies. Where nearly all deliveries occur in hospitals, maternal and child health administrators would probably rely on hospital rather than area-of-residence tabulations for pinpointing the need for special facilities.

Data on birth weight for individual hospitals is usually more informative than data for hospitals grouped according to size. They enable an investigator to pick out hospitals diverging from the usual pattern. Published analyses should refer to the distribution pattern by individual hospitals, identifying individual hospitals by code number, if necessary, as well as presenting figures for hospital groups by size of hospital.

Only one hospital was found in Connecticut (1948) where the distribution of immature birth weights deviated significantly from the State average. Where such differences are found, they should not be accepted at face value. Scales and weighing procedures in an individual hospital may have been at fault and may have biased the results. One must assess the hospital practice and the type of people it serves in interpreting the findings. In the Connecticut hospital, later developments suggested that weighing procedures were at fault.

The question has been raised whether adjusted mortality rates based on weight-specific rates should be computed for individual hospitals. In my opinion, this should not be done routinely. Where differences in birth weight distributions are small, the changes produced by adjustment are negligible. If the deviations are major, the question as to whether they are real or classification artifacts must first be answered. If the weight differences are real, use of adjusted mortality rates could be justified. Inaccurate recording of weights rewards the hospital with a lower adjusted rate than warranted (when the bias is toward lower weights) or penalizes it with a higher rate if the bias runs in the opposite direction.

Interhospital mortality comparisons are clouded in many States because of complications caused by the presence of small maternity homes, and municipal and proprietary hospitals. Maternity homes may handle mainly

uncomplicated deliveries; proprietary hospitals may draw patients from a well-to-do clientele who constitute better risks; municipal hospitals usually treat medical indigents, who may be poorer risks, and may draw the emergency cases with poorer prognosis. Under these conditions, the factor of treatment and its effects cannot readily be disentangled from selection of cases.

These selection elements are minimized in Connecticut, where no more than two hospitals were engaged in large-scale obstetrics in any community, no municipal or proprietary hospitals were involved, and maternity homes were not permitted to operate. All general hospitals in the larger cities have active staffs, and outward appearances would indicate no significant differences in types of patients admitted. For these reasons the accompanying abstract of Connecticut data (1948-50) on neonatal mortality per 1,000 live births (unadjusted) by hospital may prove interesting (table 2). Deaths are tabulated by hospitals where birth occurred, grouped according to size of hospital.

The mortality differences between hospitals

Table 2. Neonatal deaths per 1,000 live births, by hospital where birth occurred, Connecticut, 1948-50 (partial listing)

Place of birth	Rate per 1,000 live births
Total deaths in State	19.5
Deaths in hospitals:	
Total, all hospitals	19.1
Hospitals with 2,000 or more births yearly ..	18.0
No. 1	15.2
No. 2	16.3
No. 5	21.5
No. 6	21.7
Hospitals with 1,000-1,999 births yearly ...	20.5
No. 1	16.5
No. 2	18.2
No. 8	21.9
No. 9	25.8
Hospitals with 500-999 births yearly	19.3
No. 1	16.0
No. 2	16.8
No. 8	22.3
No. 9	27.2
Hospitals with less than 500 births yearly ..	18.4

cannot be attributed to chance factors. Assuming that the neonatal mortality rate for the entire State represented the true risk in each hospital, the differences between the observed and the expected number of deaths could have occurred by chance much less frequently than once in 100 trials ($\chi^2=52.6$, d. f. 24). This hypothesis must be rejected. Differences between hospital size groups were unimportant, compared to those between individual hospitals. The same results would have held if reported fetal deaths had been combined with neonatal deaths to compute combined loss ratios.

Mortality rates by individual hospitals provide a powerful tool for maternal and child health administrators. They not only point out places for improvement, but, when distributed to the hospitals concerned, stimulate the staffs to examine and take steps to improve conditions.

A standard table of major importance, useful for interarea and time series comparisons, is mortality by birth weight (table 1). The administrator will probably be most interested in following the time trends in his area for mortality in the various weight groups to see what results his program is producing. Where space permits, both unadjusted and adjusted (for unreported birth weights) weight-specific rates should be shown, so the reader can gauge the size of the correction involved. Separate presentation of neonatal mortality and fetal mortality is imperative. With differences in legal requirements for reporting fetal deaths, present interarea comparisons of fetal mortality are greatly restricted.

It is well known that sex and race influence birth weight distributions; male and white babies weigh more, on the average, than female and Negro babies (7, 8). Since female and non-white babies are generally more mature than male or white babies of equal weight, other things being equal, the former tend to exhibit smaller weight-specific mortality rates under 2,500 grams. The New York City data for non-whites bear this out.

Complications of Pregnancy and Labor

Tabular presentation should distinguish between the total births registered and the num-

ber of reports with answers to questions on complications. A count of deliveries exhibiting one or more complications should be presented, permitting comparison with the total number of complications reported. In Connecticut, the ratio of reported "complications" to "women with complications" has run between 1.10 and 1.15.

For clarity in presentation, grouping of individual complications under three major headings—complications of pregnancy, of labor, and nonpuerperal—seems desirable. The arrangement must be somewhat arbitrary because the line of demarcation between complications of pregnancy and of labor is not always distinct; for example, premature separation of the placenta could be associated either with the antepartum stage or with labor. Standard usage in the arrangement and grouping of complications can undoubtedly be developed.

The distribution of complications for plural deliveries departs noticeably from that for single deliveries and should be presented separately.

For single deliveries, complications affecting birth weights of babies weighing 2,500 grams or less should be distinguished from those for full-term babies. Further subdivision of birth weights expands the tables greatly, tends to obscure the results in a mass of detail, and should not be attempted as a routine measure. Plural deliveries are so few that the study of association between complications and birth weight can advantageously be confined to single deliveries. Data for plural deliveries could be accumulated and made the subject of a special report.

Tabulations of reports of complications by hospitals are of interest, primarily as a check on the quality of reporting from individual hospitals, taking into account any selectivity factor among patients. These reports offer the maternal and child health administrator some clues as to completeness of records maintained in various obstetrical departments. The maternal and child health administrator can use these tables as a springboard for making specific inquiries about record-keeping systems in individual hospitals. It is difficult to generalize as to where such inquiries may lead. Depending on the interest and cooperation of the hospital

staff, results might include revision of hospital forms and more frequent review of case records by chiefs of services.

In Connecticut (1948) the proportion of live births with complications reported ranged, by hospital, from 3.3 to 26.3 percent. In addition to such complications as dystocia, disproportion, and malpresentations other than breech (for which lack of precision in definition contributes to variability), reporting varied markedly for toxemias (other than eclampsia), placenta previa and other antepartum hemorrhage, erythroblastosis, and breech presentation.

Presentation of mortality data requires separate tabulation of complications for neonatal and fetal deaths. The general breakdowns for single full-term, single immature, and plural deliveries should be maintained. Preceding comments concerning separate presentation of fetal death and neonatal mortality apply here also. When the numbers observed are relatively few, consolidation of certain complications for the computation and publication of rates may be indicated. At best, such

tables are voluminous and the reader's task may be eased by arranging the complications in descending order of mortality.

Table 3 is an abstract of material on mortality according to complications. For convenience in reproducing the results, only the rates are shown. Antepartum hemorrhage was the complication of pregnancy with the highest combined mortality; hemorrhage, for complications of labor; diabetes was the leading nonpuerperal complication. The variable relationship between fetal and neonatal mortality and the mortality pattern for full-term and immature deliveries should be noted. Because of variation in reporting complications by hospitals, routine analysis of mortality by complications for individual hospitals would not be feasible.

Medical society committees and hospital staffs, as well as health departments, have always expressed keen interest in tabulations of delivery procedures for individual hospitals. In Connecticut, such data have been released, with the hospital identity concealed by code.

Table 3. Fetal loss per 1,000 births,¹ by complications of pregnancy and labor, Connecticut, 1948

Complications of pregnancy and labor	Total			Single, full-term			Single, immature		
	Combined fetal loss	Deaths under 1 month	Fetal deaths	Combined fetal loss	Deaths under 1 month	Fetal deaths	Combined fetal loss	Deaths under 1 month	Fetal deaths

¹ Rates for "combined fetal loss" and "fetal deaths" are per 1,000 total births (i. e., live births plus fetal deaths). Rates for "deaths under 1 month" are per 1,000 live births. "Fetal deaths" refer to fetuses of not less than 28 weeks gestation.

Table 4. Percentage of live births by cesarean section in Connecticut hospitals, 1948

Size of hospital (number of births)	Average (group)	Individual hospitals
Total, State-----	5.6	-----
2,000 or more-----	6.4	12.1, 7.8, 5.4, 4.8, 3.2, 1.4.
1,000 to 1,999----	4.3	8.2, 6.9, 5.4, 5.2, 4.5, 4.2, 3.0, 2.2, 1.4.
500 to 999-----	6.3	12.5, 10.9, 8.3, 6.7, 5.2, 5.1, 4.9, 2.6, 1.9.
Less than 500----	3.0	10.0, 6.0, 4.1, 3.8, 2.8, 2.4, 2.4, 1.6, 1.3, 0.9.

These data have indicated little variation by hospital for version and extraction; the tabulations pinpoint a few hospitals with high rates for this complication. The variation has been more pronounced for mid- and high-forceps deliveries, but, again, the tabulations picked out a few hospitals with rates markedly above average.

The great difference between Connecticut hospitals has been in the proportion of babies delivered by cesarean section. The figures do not appear directly related to hospital size (table 4), although the lowest proportion of cesarean sections is found in the smallest hospitals. Differences of the magnitude observed must represent differences in concepts and procedures rather than differences in problems encountered.

The concepts underlying Lembcke's recent study (9) and investigations of delivery procedures would seem to be essentially the same. Increasing attention in the future will probably be devoted to vital statistics studies dealing with interhospital variation.

The proportion of deliveries by cesarean section has increased steadily in Connecticut during recent years. A similar trend has been evident in New York City and upstate New York. Mid- or high-forceps delivery, breech extraction, and version and extraction have declined (table 5).

Because of the great interhospital variation in proportion of cesarean sections, marked changes in the trend for cesarean sections are potentially possible. Repeated tabulations on delivery procedures at regular intervals seem desirable.

Not much demand has developed for detailed cross tabulations of delivery procedures by complications, since the selection of delivery procedure is generally dictated by the complication. Physicians have been satisfied with tabulations of operative procedures by broad groupings of complications.

Neonatal and Fetal Deaths

Studies made by Yerushalmy (10) several years ago demonstrated a relationship between neonatal and fetal mortality and birth order and age of mother. In view of the declining neonatal and fetal mortality rates, presentation of current data on these points should be encouraged. Where differences in mortality by birth order and age of mother still exist, some special tabulations of complications and birth weight by these factors might be undertaken to see if they could account for all or part of the differences in mortality.

Gardiner and Yerushalmy (11) demonstrated that the risk of neonatal and fetal mortality was much higher for mothers whose child-bearing history showed previous loss of children. This line of investigation could profitably be extended to consider complications reported for such women in a current delivery and the birth weights of the babies, as well as resultant mortality.

Medical certifications for neonatal deaths rarely allude to conditions present in the mother in the sequence leading up to the underlying cause of death of the infant. This is one reason why it is difficult to reconcile cause-of-death distributions for early neonatal and late fetal deaths, which theoretically should closely resemble each other. The situation might be accounted for in part by lack of information

Table 5. Change in percentage of live births by procedures specified, Connecticut, 1948 and 1941

Delivery procedure	Year		Percent change
	1948	1941	
Cesarean section-----	5.6	3.2	+75
Mid or high forceps-----	3.6	4.2	-14
Breech extraction-----	1.6	2.1	-24
Version and extraction-----	.3	.5	-40

available to the certifying physician concerning the obstetrical history of the mother. Neonatal death certifications could be reviewed in connection with complication data reported on the matching birth certificate to see if further inferences could be drawn concerning cause of death. This might lead to improvement of medical certifications for neonatal deaths.

The last revision of the standard stillbirth certificate removed the question on time of death—before or during delivery. Some people hold that this item helps in the interpretation of fetal death statistics and that causes of fetal death should routinely be cross-tabulated with time of death. States which have retained time of fetal death on their certificates should incorporate this element into their tabulations of causes of fetal deaths.

Drawing Samples for More Intensive Study

The assessment of preventability of fetal and neonatal deaths is a project which excites the interest of maternal and child health directors. The success which has attended the investigation of individual maternal deaths to determine preventability and the subsequent confirmation, as indicated by the decline in maternal mortality rates, of the findings that many of the deaths were preventable, has led many people to believe that the same methods of inquiry should be applied to fetal and neonatal deaths. A sampling approach would be indicated since there would be too many fetal and neonatal deaths for each to be investigated.

In Connecticut, a State Medical Society Committee to Study Stillbirth and Neonatal Mortality has recently been organized with both pediatricians and obstetricians represented in its membership. Members have been drawn from a large number of hospital staffs to secure a broad base of representation.

The committee is just beginning to study a sample of neonatal deaths. Standard sampling techniques are being used to select cases for study, so that inferences from the sample can be extended to the total neonatal deaths in the State. In Connecticut the decision has been made to draw the sample in the State office. The health department physicians doing the field work find that assembling of informa-

tion through review of hospital records and interviewing physicians is progressing satisfactorily. As yet, the committee has not fixed a procedural pattern for reviewing and evaluating the material collected.

Complete work-up of individual deaths calls, of course, for microscopic examination of tissues. This, too, could be fitted into the sampling scheme. Tissues could be stored in the hospitals temporarily until after the sample is drawn and specimens then discarded for deaths not included in the sample, if the specimens are not wanted for other purposes.

Statistical Program Operations

Tabulation of the birth statistics considered in this paper consumes a great amount of personnel and machine time. Many projects await study by public health statisticians, and the allocation of statistical resources to work demanding attention is a major responsibility confronting statistical administrators. This pressure automatically raises certain questions concerning such a major activity as the medical supplement program: Must the data be processed completely every year? If not, is continuous sampling the answer? Is a cyclical approach satisfactory? Can a complete analysis be done one year, dropped, and picked up in a later year? Would a 2- or 3-year cycle of operations be needed, using the initial year of the cycle to improve the quality of responses on the medical supplement?

The problems of State offices with respect to coding, tabulating, and other handling of records make the complete processing of records in selected years the most attractive approach. Many offices would have no difficulty in building up a cycle of operations in which medical supplements alternate with such projects as multiple cause-of-death tabulations, and with special tables and rate computations for census years.

Conclusion

Many studies have been stillborn when the prospective investigators have concluded the data were too unreliable to bear analysis. No one working with the birth certificate medical

supplements has ever believed that this material was a model of statistical precision and accuracy, but this did not deter the pioneers in this field, and some benefits can now be reaped from their work.

Much has been printed recently concerning computing machines and servomechanisms which have so-called feed-back facilities. The feed-back principle should be borne in mind in essaying the analysis of medical supplement data. Material is salvaged from the initial investigations, not only for its immediate interest, but as a means of stimulating the sources of information—the physicians—and encouraging them to improve their reporting practices. With repetition of the interaction cycle between physicians and statisticians, the quality of the data can gradually be improved. The handling of the medical supplement data on birth certificates, a generally accepted health department activity, may provide useful experience to statisticians in the problems and mechanics of handling medical care data. These statisticians will later attack problems concerning the collection and improvement in quality of medical data in other fields of interest to public health administrators.

The Practice of Public Health, 1952

“WE ARE MET to reexamine our responsibilities, to analyze our progress, and to plot our future course. During our deliberations we shall discuss the health needs and problems of the people whom we serve. We shall study new scientific and social developments which should be incorporated into public health programs, and we shall analyze the progress we have made in bridging the vast gap between scientific knowledge and its application to the health needs of the people. Underlying all these discussions will be a strong sense of our stewardship for the health protection of our nations, a realization that as public health workers we have both the privilege and duty of serving the people who have entrusted us with the responsibility of safeguarding their health and have given us a specific mandate to concern ourselves with the interests of health and life among the people.”

GAYLORD W. ANDERSON, M.D., Dr.P.H.,
President, American Public Health Association, 1951-52

a topical

The APHA Conference Report

This is *Public Health Reports* third effort—the first being in 1950—to summarize the scientific and technical discussions at the annual meetings of the American Public Health Association and related organizations. We consider it a privilege so to serve our readers, many of whom have expressed their satisfaction with our previous efforts, and to be able to carry on as urged by the Executive Board of the Association.

The earlier pattern of a news-type reporting of the highlights of many of the sessions has been followed in this presentation, the second portion of which will appear next month. We have attempted to give the essence of the papers, but by no means the complete story in each case. We have endeavored to reflect accurately the intent of each speaker although necessarily we have had to take extensive editorial liberties in the interest of brevity and under the press of time. It must be clear, of course, that the author—not the Public Health Service—is the authority in each case for facts and opinions reported.

This is a selective report, largely because we work from authors' written texts as made available through the pressroom facilities of the Association at Cleveland, and by authors on direct request. Material which was not available in satisfactory script form obviously could not be used. Reporting of informal panel-type discussions is, in consequence, incomplete.

The report this year is, item by item, somewhat longer and possibly more complete than in the past since virtually all summaries were prepared from full texts. Even so, only highlights could be reviewed, reports averaging in length from 10 to 15 percent of the originals. Thus, reading of our news-reviews cannot in any way substitute in concept or details for examination of the full papers when published.

This special two-part section deals only with the scientific sessions. Association and section business and reports have not been reported, this being a function of the official *Journal*. No full papers, of course, are published in this summary report. Complete texts of leading papers have already begun to appear in the *American Journal of Public Health*. Subsequently, others may appear in *Public Health Reports* and in appropriate specialty journals.

Our appreciation is extended to the many authors who provided us with texts—especially those who did so early—and to the officers and staff of the American Public Health Association for their cooperation and encouragement.

THE EDITORS

policed—the description and exemplification of successful methods of preventing the progress of pestilences by stamping them out, the mapping out of the course of epidemics, and the demonstrated progress of science which is destined to grapple successfully with the combined factors of epidemic and other preventable diseases, show how great are the tasks and the triumphs which Preventive Medicine has proposed. . . .

Sanitary officers and boards of health have to perform their duties under laws which, in most of the States, are not worthy of an enlightened people. A sanitary system worthy of the present state of the physical sciences and of hygiene hardly has existence in any of the States. But in eight States a central Board of Health has begun its work of inquiry and the framing of a project of public health laws, a parliamentary commission in the Dominion of Canada is at present devising a sanitary code, and in nearly half of the States of our Union efforts to secure good laws and a sanitary system have commenced. Certainly it is not in vain that the American Public Health Association pursues its voluntary inquiries and now presents these contributions to a great cause in which philanthropists and statesmen are enlisted as co-workers with medical and sanitary authorities.

—ELISHA HARRIS, M.D., secretary of the Association, in an "Introductory Note" to "Public Health Reports and Papers presented at the meetings of the American Public Health Association in the year 1873."

The Control of Chronic Illness and Efforts in Rehabilitation

Chronic illness and rehabilitation were among the leading topics discussed by the some 4,000 professional people in public health who participated in the APHA's 80th annual meeting in Cleveland, Ohio. From Georgia came a report on a cardiac control program; from North Carolina came news of diabetes control clinics. Investigators in Canada reported on social and environmental factors in multiple sclerosis. Incapacitated American coal miners do not take kindly to enforced idleness nor public assistance, and a total physical medicine and rehabilitation program can realize important social and economic savings . . . such were some of the findings, summarized in the following.

Cardiac Clinic Network Feature of Georgia Plan

The cardiac control program developed in Georgia has, in the opinion of J. Gordon Barrow, M.D., director of the cardiac clinic at Grady Memorial Hospital, Atlanta, done more to advance the fight against heart disease than would have been possible by any other means with such a small expenditure of money. The program, made possible by the combined efforts of many individuals and agencies, both public and private, includes a State-wide network of clinics for diagnosis and care of indigent patients, professional education, and research.

When the program began, Dr. Barrow stated, only two cardiac clinics existed in the State, one at each of

the two medical schools. These were made into strong regional clinics with the intention that they would provide consultation services and diagnostic and treatment facilities for local clinics. At present eight local clinics are in operation and three more are ready to begin.

Initial Steps

Outlining the steps taken to develop a local clinic, he listed these: find qualified physicians willing to devote their time without charge to the operation of the clinic; obtain approval of the project by the local medical society; enlist the aid of the local health officer; and finally, call a conference of representatives of the State health department and the State heart association, the local physicians who have volunteered their services, the local health officer, and often members of local civic organizations to formulate final plans.

These clinics, according to Dr. Barrow, provide diagnosis and treatment, including surgery; utilize methods of prophylaxis to prevent heart disease or halt its progression; give medical, nursing, and social service care to patients with serious heart disease; provide a home-care program; and aid in rehabilitating patients. The average total number of patients visiting the clinics per month has been 2,911, Dr. Barrow reported. Home nursing visits average 830 per month. On the average 31 doctors attend each clinic session, of which there have been 82 per month.

A system of recording the diagnosis and functional and therapeutic classifications of each patient was devised, following the standards of the American Heart Association, Dr. Barrow explained. Copies of notes made by the physicians are sent to

the nurses in the field, and the nurses' reports are made available to the physician. "We feel that each member of the medical team must be fully familiar with what is going on if proper follow-up of the patient is to be accomplished," Dr. Barrow maintained. "Good records are the only possible way this can be done."

Professional Education

Discussing the educational phase of the program, the speaker noted that in the past 2 years more than 25 symposiums have been held under the sponsorship of the State health department and the State heart association to acquaint physicians and nurses with recent advances in heart disease therapy. He mentioned also that the clinics have co-operated in the educational program by holding staff conferences for the nurses and physicians and by making available their facilities for use by medical students.

"The research program is necessarily centered at the two medical schools," Dr. Barrow pointed out. At present several different cardiovascular research projects are under way. But, he added, each clinic is urged to sponsor clinical research programs since these require only carefully kept records and critical analysis.

Many Served Economically in North Carolina Clinics

The belief that the operation of a clinic for diabetes offers an opportunity for the public health department to do much good for many people for a comparatively small expenditure of money was expressed by W. B. Hunter, M.D., health officer of the Harnett County Health Department, Lillington, N. C.

"Six years ago," Dr. Hunter said, in describing the beginning of the Harnett County Health Department's clinic, "we found some diabetic patients who were not receiving adequate care. We helped a few

of these people with such gratifying results that . . . we soon found ourselves conducting a clinic for diabetes." Later, he explained, it was decided to admit obese patients too, since obesity and diabetes are closely related. The clinic has had a total of 506 patients, well over 1 percent of the county's population.

The management of diabetes is preventive medicine, Dr. Hunter pointed out. Physicians do not treat diabetes—they teach the patient how to manage his own individual case, he said. The objective is to prevent complications and to keep the patient as near normal as possible.

Clinic Procedures

When a new patient is admitted to the clinic, he continued, he is weighed, his height is measured, and his ideal weight is estimated. A urinalysis and a blood sugar determination are done. Usually, these data establish the diagnosis, show whether the patient is overweight, and give some indications of the severity of his disease. If it appears that the patient will require insulin, he is taught how to administer it. Finally, he is given instructions concerning diet. At this first visit, then, the patient is well started on the management of his disease. At subsequent visits the insulin dosage is regulated according to results of urine tests and occasional blood sugar tests. Diet is regulated according to the gain or loss of weight.

Describing the diets prescribed by the clinic, Dr. Hunter emphasized that they are simple and versatile. Diabetics do not require any special foods, he said, but if overweight they must restrict the total calories they consume. For several years, the clinic has used exclusively the meal plans and the booklet "Meal Planning," prepared by the American Diabetes Association, the American Dietetic Association, and the Public Health Service, as a basis for their diet instructions.

Dr. Hunter recommended that the staff for a diabetes clinic include a

physician, a dietician, a laboratory technician, and a clerk. The physician may be either the health officer or a clinician employed for the purpose. And, as happened in the Harnett County Health Department clinic, the nursing personnel may learn to serve as dietician and laboratory technician.

Social Factors Absent In Multiple Sclerosis

A comparative study of 112 multiple sclerosis patients and a selected control group of 123 representative individuals in Winnipeg, Manitoba, found no environmental or social factor that could be considered significant in the etiology or subsequent course of the disease, reported Knut B. Westlund, M.D., M.P.H., and Leonard T. Kurland, M.D., Dr.P.H.

Dr. Westlund is research associate of the department of epidemiology, Johns Hopkins University School of Hygiene and Public Health and Dr. Kurland is an epidemiologist with the National Institute of Mental Health and medical director of epidemiological projects, National Multiple Sclerosis Society.

Information obtained from each patient, they explained, included a thorough chronological and clinical history and description of himself and his illness, embracing such facts as important symptoms, previous illnesses, places of residence and number of rooms and persons in the households, occupations and hazards involved, emigration origins of himself or ancestors, travel, education, military service, exposures to animals, vaccinations and inoculations, and dietary habits.

Neurological and hematological examinations and serological tests for syphilis were made and the patient's hospital records were studied. No attempt was made to evaluate the influence of emotional upsets or minor trauma in the patient's pre-morbid experience, since it was felt that both the patient and his physician might tend to rationalize the

onset of his disease symptoms with such explanations. Except for questions relating directly to multiple sclerosis, similar information was elicited from the control subjects.

A comparison of the data showed no significant difference between the patients and the controls which might account for the onset of multiple sclerosis, the epidemiologists concluded. A controlled study of a large number of healthy people with a long follow-up period to see what types of them develop multiple sclerosis would be desirable, they added, but its incidence of 1 to 2 cases per 100,000 population per year is so low that the investigator can only obtain and try to evaluate pre-morbid information from persons already having the disease.

Rehabilitation Program For the Incapacitated

Incapacitated industrial workers do not remain unemployed or unemployable by choice, nor do they prefer to support their families through public assistance if there are any reasonable alternatives, declared Kenneth E. Pohlmann, rehabilitation director of the United Mine Workers of America Welfare and Retirement Fund.

UMWA rehabilitation efforts were begun in June 1948, said Mr. Pohlmann, by using outside (the mining areas) medical center services for the severely disabled, followed by expanded efforts when further needs, such as physical restoration services, were indicated. Subsequent steps included cooperation with Federal-State vocational rehabilitation agencies whereby selected patients, were referred for rehabilitation services to qualified agency representatives. By June 30, 1952, 8,693 handicapped people had been so referred by the UMWA.

As an example of the rehabilitation program's effectiveness, he continued, of 738 UMWA disabled beneficiaries leaving physical medicine or

rehabilitation centers by January 1952, 600 (81.3 percent) are still in discharge status and 169 are actively employed, 20 percent of them returning to mining. Thirty percent are in other industries, 32 percent are self-employed, 7 percent are in farming, 4 percent sought appointive or elective offices, and 8 percent are in diverse jobs.

Follow-up Care

All persons discharged from such centers are given extensive follow-up study and care by local physicians, hospitals, or one of the UMW's 10 area medical staffs, Mr. Pohlmann said. Half of the 738 discharges show marked physical improvement, 43 percent have maintained various rehabilitation gains, and an impressive number have regained mobility with mechanical aids or are capable of self care.

Sixty-four percent of the 575 patients referred to local vocational rehabilitation groups participated in training and employment services. Only 18 percent quit because of physical regressions and unsatisfactory vocational goals. Mr. Pohlmann emphasized that if the 169 of these participants now employed were public assistance charges, the maintenance cost of each individual and family would be 500 to 1,400 dollars per year. This would entail a tremendous expenditure for the entire group over a number of years, he said.

Present workmen's compensation, relief and rehabilitation programs are inadequate to do a constructive job in rehabilitating the severely disabled, he concluded.

Washington, D.C., Solving Problems of Disabled

A total physical medicine and rehabilitation program offers the community an opportunity to realize significant economic and social savings and, more important, to help restore to the disabled person that

human dignity which is lost to the helpless and the dependent, declared Josephine J. Buchanan, M.D., of the Division of Chronic Disease and Tuberculosis, Public Health Service.

The Program

To show how such a program can be developed and what it can accomplish, Dr. Buchanan described the program begun 2 years ago at Gallinger Municipal Hospital in Washington, D. C.

"We began with two things," she said, "the barest minimum in personnel, space, and equipment, and a firm belief in the validity of the work we proposed to do." She explained that the philosophy on which the program is based is that a patient is not well until he is returned to his community as nearly a whole human being as our science, our work—and equally important, his effort—

can make him. To cure a patient of a disease or heal him of an injury is but the first step in the total treatment of a patient.

Home-Made Devices

Certain basic specialized medical equipment had to be purchased, she remarked, but the greater part of the equipment was built by the hospital: devices for lower and upper extremity exercises, parallel bars, practice stairs, and various self-help devices. A "gadget board" holding items, such as a dial telephone, water-faucet handles, and light switches, was devised for persons with residual disabilities in their hands and arms. An outdoor functional activity area, including a gravel pit, loading platform, garden, obstacle course, and even a city bus, was also developed, primarily for training those who earn their living by manual labor.

"Our Basic Mandate . . . To Keep People Well, Not Simply Keep Them Alive"

In his APHA presidential address, Gaylord W. Anderson, M.D., Dr.P.H., Mayo professor and director, School of Public Health, University of Minnesota, said:

"Many definitions of public health have been advanced, but probably none so simply or so clearly expresses the will of the people as the 1869 statute establishing the Massachusetts State Board of Health and instructing that board to 'take cognizance of the interests of health and life among the citizens.' No other concept has had comparable influence in shaping the course of the public health movement in this country . . . [It] has governed the evolution of public health and still defines the scope of our activities . . ."

"Public health is an organized community program designed to prolong efficient human life. It has no artificial limitations that would restrict its activities to certain types of problems. It must deal with and endeavor to combat those forces that tend to impair or to shorten efficient human life and must meet each problem according to its particular needs. The essence of democracy is the concept of rule by the people, who have a right to protect themselves against all forces that lead to illness or to death. As public health workers and servants of the people we have been specifically instructed to 'take cognizance of the interests of health and life among the citizens.' If we neglect or fail to do so we will be derelict in our duty."

(Dr. Anderson's remarks appear in full in the *American Journal of Public Health* for November 1952, pages 1367-1373.)

The development of special devices, Dr. Buchanan pointed out, requires only a knowledge of the needs of the patient and the ingenuity to fulfill those needs.

Most important to remember, she said, is that "this newest and oldest form of medical care" must begin immediately with the onset of the disabling condition and must progress concurrently with the patient's other medical care. Delay in beginning treatment may mean failure.

60.9 Percent Independent

The program has given care to about 2,000 patients, she reported, 60.9 percent of whom have left the hospital totally independent and another 21.6 percent have been made partially independent. She mentioned two particularly dramatic cases—one, a young quadriplegic who, through the use of a special splint, has been enabled to take up cartooning; the other, a young man paralyzed in a swimming accident who now manages to type his correspondence school lessons.

Suggests Activities

Dr. Buchanan suggested the public health officer, or other member of a health department staff, as the person in the community to stimulate action in developing a program of physical medicine and rehabilitation. He can acquaint the community with the ways in which total restorative and rehabilitation services can help solve the problems which surround the disabled. He can participate on health and welfare planning committees. He can offer consultation service to his local vocational rehabilitation office and to the welfare department. He can encourage physicians to extend their limits of responsibility to the disabled patient. He can encourage the voluntary agencies to join together in planning for such a program.

Community Organization for Health: Practice and Precept

Concepts of "community organization for health" received refurbished definitions buttressed by concrete examples of cooperative action from widely separated areas of the country at sessions of the Conference for Health Council Work.

Under the title, "Community Planning for Local Health Services," reports were heard from Wisconsin, Massachusetts, Ohio, Pennsylvania, and Virginia. An evaluation of current concepts and a discussion of local relationships to national programs completed the presentations, all but one of which are reviewed below.

Community Organization Welds Social Groups

Discussing "new concepts" in community organizations for health—concepts which he felt were not new but did need review—Earl Lomon Koos, Ph.D., chairman of the sociology department of the University of Rochester, said:

"Community efforts directed toward better health are necessarily custom built. . . . Community organization for health cannot be carried on in an icy apartness from the social worlds in which the people live for whom it is designed, and because community organization cannot ignore the strength of the factors which create distinctive values regarding health, and which place

those values high or low in the whole hierarchy of values that are part of American life. For we must remember that health is a value—and one which is forever in competition with other values in our society."

In Dr. Koos' view, community organization is a form of activity which attempts to "weld together" the individual members and groups of an area into "one group having a common purpose." He went on to discuss two kinds of concepts: those related to the individuals and groups, and those related to community organization as a social process.

Three Community Groupings

There are several types of identifiable groups in the community, Dr. Koos pointed out. The first centers in "ethnic identification," that focused upon the recognition of a common religious, nationality, or racial characteristic. "To plan programs without understanding the prescriptions and proscriptions of behavior which are present in each group's culture is to be unrealistic about what can be accomplished through formal organization."

"Ethos identification" is a second group, pointing up the reality of social class membership, the sociologist noted. He called attention to a recent study of a community of less than 5,000 which shows "that there are sharp differences in health attitudes and behavior among the social strata of that community, and that these relate very directly to the way in which that community organizes for health."

The third grouping centers on the family, which functions as an active agent in providing an atmosphere in which health can flourish and as an agent in caring for the individual in time of illness. Dr. Koos underscored the fact that the family also, "is the matrix within which many basic ideas and attitudes of the young are formed, and that it is genuinely effective in maintaining such ideas and attitudes throughout the adult years."

The Family Matrix

"We may well search," Dr. Koos went on, "the logic of industry- or school-centered programs that ignore the importance of the family as a 'conditioner of attitudes,' and that may send the individual back into his family to face conflicting ideologies about health and its value. . . . Such programs can work effectively only if they send the individual back to his family prepared to adjust differences that may have been engendered, to make him, in effect, a health organizer in his own small family world. If the individual is not so prepared—because the health program ignores the individual's emotional ties to his family—the cost in tensions and frustrations can outweigh any small good the program may have accomplished."

Turning to community organization as a social force, Dr. Koos recalled the truism that the individual gains from his membership in the group, and contributes to that group, only in proportion to his participation. The condition for effectiveness was described as an "atmosphere" in which the members have high morale, the opportunity and encouragement to communication with each other on a democratic basis, and the opportunity to "define the situation" or to "establish common values" on equal terms.

Conversely, the speaker pointed out that there are three concepts that can only inhibit effectiveness. One of these, he said, is the idea of the "hierarchy of ability," the belief that "we know what is best for people." Another is the "vested interest, that pride of possession and proprietary interest that tends to exclude others from dynamic participation." The third he cited as "the domineering need to dominate, characteristic of many individuals who stem from the authoritarian past."

"We cannot deny," Dr. Koos maintained, "that there is a hierarchy of ability, but it should be pointed out

that special abilities and knowledge should serve only to commission those who possess them to help the less fortunate to gain needed insights. It is not easy for many members of the community, especially those with a strong sense of *noblesse oblige*, to rid themselves of the second and third of these concepts, but somehow community organization must find the means—again through the group process—by which these can be abolished."

Milwaukee Groups Study Postwar Problems

Milwaukee County, Wis., like other metropolitan areas, faces public health problems resulting from postwar expansion and has begun to interest itself in community health planning, declared John S. Hirschboeck, M.D., dean, Marquette University School of Medicine. The citizens themselves, their elected county officials, public and private health agencies, and the Community Welfare Council of the city of Milwaukee are cooperatively planning public health programs.

County citizens and part-time health officers of the 18 suburban communities were opposed to a suggestion for a combined city-county health department. Despite some opposition, but facing an increasing number of complaints about inadequate sewage disposal, the Milwaukee County board of supervisors created a citizens' committee to study county public health needs, explained Dr. Hirschboeck. The citizens' committee, with the help of the research department and the social planning committee of the community welfare council, searched for a way to meet present public health needs without disrupting existing suburban programs.

Dr. Hirschboeck outlined the committee's proposed plan: A county bureau of health services would operate under the direction of a full-time public health officer. According

to their requirements, suburbs would purchase services from the bureau. The cost of operating the bureau would be prorated among the participating suburbs. The bureau would be responsible for sanitation in the county parks and would supervise medical aspects of civil defense planning. Hearings on the proposals have not been completed.

Ohio Emphasizes Local Health Planning

In Ohio, State public health planning is being stimulated by 50 community health councils and by many local units organizing health councils, reported Sewall O. Milliken, M.P.H., chief, division of public health education, Ohio Department of Health. Rural Ohio counties have received nation-wide acclaim for their health studies and successfully executed plans, he said.

Active local participation in State health planning is the concern of the Ohio Rural Health Council, organized in 1941, explained Mr. Milliken. Composed of 46 members represent-

ing 22 State organizations, an equal number of elected rural members, and 2 representatives of the Agricultural Extension Service, the council has developed a definite relationship between State and local community health service planning, by placing emphasis on local responsibility and by aiding local activities. Health education, dissemination of health information, the training of leaders, and study and survey of individual area health needs are projects under council sponsorship.

Other Organizations

The Ohio Committee on Public Health, an outgrowth of the Ohio Rural Health Council in 1949, studied the State's financial obligation to local health departments as provided by law. Other public health organizations cited by the author for their interest are: the Ohio Citizens' Council for Health and Welfare, the Ohio Public Health Association, and the State Planning Committee for Health Education.

An example of productive responsibility shared by several organizations is the brucellosis control pamphlet which Mr. Milliken de-

scribed as prepared cooperatively by the Ohio State Medical Association, the Ohio State Veterinary Medical Association, the State Departments of Health and Agriculture, and the Ohio State University Agricultural Extension Service.

Council Improves Services

Reorganization and expansion of city, county, and suburban health departments, a children's mental health center, hospital construction, a tuberculosis registry, a 5-year experiment in mass health education, institutes and courses in community health programs—these are among the accomplishments credited to the Metropolitan Health Council of Columbus, Ohio, according to the report by Russel G. Means, M.D., past president of the council.

Pennsylvania Revamps Laws and Structure

The revamped Health Department of Pennsylvania was described before the Conference for Health Council Work by Gilson Colby Engel, M.D., professor of clinical surgery,

The first 5 decades of America's 20th century have been a time of social and economic change and development . . . a time of population growth, sparked by immigration and the call of a free and bountiful land . . . a time of industrial expansion and urbanization, producing a rising standard of living and a greater longevity. This half-century has been a time of change and challenge to a new amalgamation of professions: public health. In these 50 years many needs, many problems came into view.

1900 Tuberculosis is leading single cause of death . untreated water, unpasteurized milk spread enteric diseases . one-third of all deaths occur under 5 years . 19,000 diphtheria deaths . heart disease and cancer deaths increase . influenza epidemic strikes Nation . pellagra, rickets, goiter prevalent . 9 mothers die for 1,000 live births . traffic deaths appear among "first 10 causes" . malaria costs Nation half-billion dollars annually . 100,000 smallpox cases in 1921 . health hazards in industry mount . chronic diseases

1930 cause half of all deaths . over 500,000 VD cases reported each year . half of Nation's hospital beds for mental patients . 6 million sick on average winter day . **1940** disabling illness rivals premature death . shortages in personnel and facilities hamper health services . proportion of 65-year-olds doubles since 1900 . industrial and **1950** community wastes pollute United States waters . atomic age introduces new problems . health named a major factor in building international peace.

Beginning on the facing page, Part I of this album summarizes recognized needs and primary programs up to mid-century. Part II—next month—focuses on current and developing areas with an eye to tomorrow.

University of Pennsylvania Graduate School of Medicine, Philadelphia.

The Medical Society of the State of Pennsylvania, the 46 member organizations of the Pennsylvania Health Council, and the League of Women Voters were instrumental, he said, in the campaign for new health legislation, and the changes in the State's health organization were based on recommendations made in a survey by the American Public Health Association.

The APHA survey, "Keystones of Public Health in Pennsylvania," was used as a guide for the public health program reforms, Dr. Engel continued. The new laws created an Advisory Board of Health which advises the Secretary of Health and plans and fosters new health legislation; a merit system, applying to all public health personnel, to assure permanence of employment, equality and adequacy of pay, and impartial treatment, and to make provisions for economic security upon retirement; permissive legislation allowing any community to set up its own local health unit.

Community Units

The objective in Pennsylvania is to decentralize health services to the local level, with power to control at that local level, stated Dr. Engel.

The permissive legislation allows a community to set up its own health department, Dr. Engel explained. This local health unit, using qualified personnel, should provide six basic services: vital statistics recording; communicable disease control; environmental sanitation; laboratory services; maternal and child health care; and health education. One such unit now operating in Butler County is showing good progress, he said.

The Pennsylvania Health Council works closely with the Secretary of Health and the Advisory Board of Health. It is fostering the local health unit plan in communities by education programs.

In Pennsylvania 78.4 percent of the population are covered by five

Blue Cross plans, the Intereounty plan, and commercial carriers against hospital costs. A Blue Shield plan is State-wide in activity and growing rapidly in membership.

"Health education is the prime step in making the citizens health conscious, and it is only when they become health conscious that we get real support in projects for prevention of illness," concluded Dr. Engel. "The educational job with the public is monumental and never ending as new generations are born."

Rural Health Progress Noted in Virginia

Growing out of the need of rural people for more adequate medical services, the Virginia Council on Health and Medical Care has stimulated health progress in Virginia since its beginning in 1946, Edgar J. Fisher, Jr., director, told the Conference for Health Council Work.

Mr. Fisher listed many accomplishments. The council, he told the conference, has:

Spearheaded and promoted an over-all health program with emphasis on coverage of the State with public health services. Now 91 of the 98 counties have full- or part-time health officers.

Centered attention on the mentally

ill in State mental hospitals. Institutions are becoming hospitals.

Taken the initiative in getting acceptance of the Hill-Burton hospital program, hospitalization of the indigent, and the regional hospital plan through which interns from the two medical schools are rotated to seven hospitals in the State.

Assisted Negro hospitals in meeting American Medical Association standards for approved internships.

Worked for tuberculosis and cancer control, transforming beds in sanatoriums from pavilion to hospital type and establishing 11 tumor clinics.

Supported programs for medical, dental, and nursing scholarships (50, 4, 74, respectively) offered alike to white persons and Negroes. Doctors pledge a year of rural practice for each year of scholarship.

Aided medical colleges in improving facilities for training health personnel; encouraged teacher training institutions to build adequate health curriculums.

Recognized the need for recruitment of medical auxiliary personnel, beginning at the high school level, and adequate salary schedules to make recruitment possible.

Inaugurated a nationally recognized physician placement service administered by the council to encourage doctors to settle in rural areas.

Sponsored a conference for workers with handicapped children as a result of which the Nemours Foundation has granted a substantial sum for strengthening the program.

Helped local health councils get started and interested the nutrition council in becoming a standing committee of the health council.

Health Programs Depend On Citizen Participation

Health councils are formal expressions of the trend by which public health has become a community endeavor and has ceased to be the exclusive domain of professionals, Harald M. Graning, M.D., regional medical director, Federal Security Agency, Region V, Public Health Service, told a joint session with the Conference for Health Council Work.

Public health has broadened from the control of contagious diseases to treatment of delinquency, mental and emotional disturbances, ills of the aging, obesity, and alcoholism, Dr. Graning remarked. The expansion of health planning is observed

in such national programs as that on aging, he noted. Medical research and medical treatment are the core of any planning, but the aging program's broad sociological scope takes it "beyond the embrace of medicine," he said.

Dr. Graning said that the consequences of the decreases in communicable diseases are to be seen everywhere and noted that the professional, the specialist, and the laboratory isolate are more and more sharing the field with those who practice where medicine allies itself with the social sciences. The effect is to think in broad concepts rather than specific disease entities when planning the integration of local, State, and national programs, he believes.

Council's Impact

Conquest of the social problems of disease depends to a major degree on community participation in health services, the regional medical director stated. There is a practical value in selecting members of the community for service on health councils, for they are often in a much better position than professional or official members to see a

program in its entirety and to identify any lack of balance or excess emphasis on professional specializations, he advised. Citizens with executive capacity and budget experience or with knowledge of resources and relative needs in program fields and welfare areas could increase the competency of a health council in fiscal and budget matters, Dr. Graning said.

"Participation in a health council by nonmedical members of the community may be vital in recalling the professional to the felt needs of the community which may be quite different from what he imagines them to be or perhaps even wants them to be," Dr. Graning asserted.

The effectiveness of health councils will be multiplied by their gaining acceptance before legislative committees or budget groups prior to decisions which may mean the life or death of a program. Many councils have permanent committees on legislation to analyze Federal, State, and local legislation affecting health programs. "If there is any more important job than this, which a council or its legislative committee can do, in relating its own plans to other health programming, I do not know what it is," said Dr. Graning.

New Research, Service Roles For the Bacteriologist

The increasing development of antibiotics and their widespread use is creating new problems for, and laying new responsibilities upon, the bacteriologist and his laboratory. But these are only a few of the newer and expanding areas of activity in which the laboratory figures, as shown by review of the many papers and discussions presented before the

APHA laboratory section and related groups.

Laboratory Has Share In Therapy Guidance

The introduction of new antimicrobial agents has caused a shift in the responsibility incumbent upon the bacteriologist, said Frederick C. Fink, Ph.D., coordinator in the

hospital laboratory advisory service of Chas. Pfizer and Co., Inc., Brooklyn, N. Y.

The speaker based his remarks on the antibiotics conferences held in 100 large cities in this country and Canada at which antibiotic testing authorities discussed the observations made in the bacteriology laboratories of medical schools, public health facilities and hospitals, and industry.

Mr. Fink pointed out that now the laboratory faces the tremendous problem of guidance for antibiotic therapy after the cause of infection is discovered by the clinician. In shared responsibility, the clinical-diagnostic laboratory and the industrial research facilities are develop-

ing assay techniques and sensitivity tests—reliable indexes to the therapeutic effectiveness of antibiotics, he said.

Historical Stage

The past 20-year history of laboratory bacteriology was divided by Mr. Fink into three stages: the pre-sulfonamide, the sulfonamide to penicillin, and the penicillin to "broad-spectrum" antibiotic (chloramphenicol, aureomycin, and terramycin). During the first stage, a bacteriology laboratory received clinical specimens, made and studied smears and cultures, and then made a report. With the etiologic agent thus identified, the clinician usually decided upon the course of therapy from among the palliative or specific curative drugs at hand.

Soon after the clinician and bacteriologist became aware that some cases did not respond to sulfonamide therapy, Mr. Fink continued, researchers developed in vitro sulfa sensitivity tests on pathogen isolates. Doctors then found that in vitro tests, using the entire family of available sulfonamides, saved much haphazard choosing of drugs to suppress infection.

Antibiotics

From the extension of the original work on penicillin came the antibiotics. Mr. Fink explained it was soon learned that many of the sulfa-resistant organisms were penicillin-sensitive and that many of the penicillin-resistant strains were sulfa-susceptible. Carefully performed laboratory sensitivity tests predict the response of organisms, Mr. Fink indicated. The broad-spectrum agents, bacitracin, polymyxin, streptomycin, and others, each with a slightly different spectrum of activity and varying degrees of toxicity, are used for routine check of microbial sensitivity in vitro.

Techniques in laboratories will continue to be determined by the mode of performance and the validity of conclusions, Mr. Fink said.

The ideal sought by scientists hinges on the care with which they select for adoption the newly described techniques of other workers, and the manner in which they approach and tackle original research problems.

Popular Tests

The three most popular techniques for in vitro testing, the broth dilution, the agar dilution, and the agar diffusion (disc-plated) methods, have in common six features which Mr. Fink lists as: inoculum; preparation and storage of antibiotic stock solutions; choice of diluent medium; pH of the medium; time and temperature of incubation; and interpretation of the tests.

"Whichever technique is adopted, it should definitely be standardized for that laboratory with respect to the inherent variables," he suggested. "We must more often rely upon information from the laboratory as we realize the existing response variation among species of the same genus or among strains of the same species."

Mr. Fink stressed that the only absolute criterion of success or failure in the use of one or another sensitivity testing technique is the clinical response of the patient following administration of adequate dosage of the agent indicated as "drug of choice."

Laundry Recontamination Hazards Emphasized

Laundry processes are efficient in removing bacteria from fabrics during washing, but the materials become recontaminated in the spin dryer or while hanging in the laundry to dry, reported Brooks D. Church, M.S., and Clayton G. Loosli, M.D., of the preventive medicine section, department of medicine, University of Chicago.

In an extensive bacteriological study in two laundries—one hospital and one commercial—it was found that during the sorting of linen and other activities the air became contaminated with bacteria and in turn contaminated clean woolen blankets and fabrics.

Also, airborne bacteria were drawn through the spin dryers and impinged on the washed textiles, and while large numbers of organisms were killed in ironing, many survived. One factor in survival, they stated, is the extraneous dried mucus covering the bacterial cell.

The findings in this study are of public health importance, they maintained, because the surviving organisms, mainly nonhemolytic and alpha streptococci and *Staphylococcus albus* and *S. aureus*, are all potential human pathogens. Clean

antituberculosis campaign

Trudeau's "Little Red"

linen which has been recontaminated in the laundry may be the source of serious infections in hospitals and military barracks.

Authorities should recognize the danger of recontamination of washed bedding by airborne bacteria dispersed while sorting and handling unwashed linen, they concluded, and should institute preventive measures by requiring proper construction, ventilation, and management of laundries, both hospital and commercial.

Solid Immunity Provided By Diphtheria Toxoid

A high level of immunity to diphtheria and tetanus can be induced in adults by small, properly spaced doses of precipitated diphtheria toxoid, Geoffrey Edsall, M.D., director of the Commission on Immunization, Armed Forces Epidemiological Board, Walter Reed Army Medical Center, and J. S. Altman, com-

mander, Medical Corps, United States Navy, reported.

In an investigation of diphtheria-tetanus immunity, 1 Lf-unit doses of precipitated or adsorbed diphtheria toxoid were given to 519 volunteer Navy Service School students, they stated. The first two doses were administered 3 weeks apart, the third, 5 months later. Antitoxin titers were determined before the first and third doses and after the third dose. After the third dose, they said, 250 of the 252 men who completed the study showed solid immunity.

Antibiotics Assayed By Serial Dilution

The application of antibiotic therapy for the control of infectious diseases necessitates the adaptation of antibiotic assay methods to routine

use, maintained Carolyn R. Falk, B.S., bacteriologist in the New York City Department of Health. In the past 9 years, the antibiotic testing unit of that department has tested more than 2,700 organisms for antibiotic sensitivity and over 10,000 body fluids for antibiotic level, Miss Falk reported.

The laboratory technique found to be the most practical for both tests is the test-tube twofold serial dilution method. It is easily mastered by the average technician, affords more quantitative results than the disc-plate method, and distinguishes between bacteriostatic and bacterial levels, Miss Falk stated.

She described the method briefly, pointing out that the tests for the new antibiotics follow essentially the same pattern as those for penicillin and streptomycin. In determining possible effective pairs of antibiotics, the scheme suggested by Jawett and co-workers is of assistance, Miss Falk said.

Experience With Home Care In Four Large Cities

Planned medical care at home offers striking promises of economy of operation and satisfaction for patients and relieves pressures on hospital occupancy, but many problems remain—particularly those involving the financing of services for the medically indigent.

These were among the main points presented before a joint session of the health officers, medical care, and public health nursing sections of the APHA, with the Conference for Health Council Work.

Boston's Voluntary Plan Has Financing Problem

Financing medical care for the medically indigent remains an unsolved problem for a voluntary project, Henry J. Bakst, M.D., indicated in a discussion of a home care pro-

gram that meets the dual purpose of serving the needy and providing a vehicle for medical education.

Dr. Bakst, professor of preventive medicine at the Boston University School of Medicine and director of home medical and out-patient services for the Massachusetts Memorial Hospitals, based his observations

largely upon the long experience of the two institutions. A home care program for the needy and medically needy has been a joint activity since 1875.

Public relief agencies financed by Federal, State, and local funds help the totally needy meet the cost of medical care, Dr. Bakst explained. But this group, he said, makes up only one-third of the annual patient load of the Boston home medical service, about 35 percent of the 15,173 home calls made in the 12 months from April 1950 to March 1951.

The Medically Needy

Two-thirds of the visits are made to the medically needy—persons who are able to provide for ordinary day-to-day needs but cannot meet medical costs, he said. Usually, nonofficial agencies, such as the hospital volunteering the service, must subsidize the medical care for this group, he stated.

Outlining the Boston program briefly, Dr. Bakst pointed out that eligibility for admission for out-patient treatment in the medical school-hospital program is based on an income limitation of \$40 a week for a single person. Groups of senior medical students provide the medical service under the supervision of two full-time second- and third-year residents and the staff of the department of preventive medicine. The service is supplied on request to eligible persons among the 50,000 in the square-mile area surrounding the hospital and school.

From November 1949 to October 1950, 84.23 percent of the patients were treated at home, 8.83 percent were referred to the out-patient department for further evaluation, and 6.94 percent were admitted to the hospital.

Six Basic Elements

Dr. Bakst named six requirements as essential to a home care program:

1. The services and resources of a general hospital.
2. Coordinated use of community resources such as the visiting nurse association, the health department, the family society, and other official and voluntary health and social agencies.
3. Centralized administration with emphasis on continuity of care and unit records.
4. Integrated cooperation of professional personnel—especially the physician, visiting, public health and school nurses, and the medical social worker—for consideration of the patient as a social being in his environmental setting.
5. Specific geographic area of responsibility in the larger cities.
6. Adequate financial support, with particular attention directed to the problem of medical indigency.

Dr. Bakst noted that hospitals participating in a home care program extend their services beyond the institution walls and add a real contribution to the health of the community. Such a program becomes, in part, the nerve and com-

munications center of personal health services for the community area, he said.

Hospital Stay and Costs Reduced by D. C. Project

Home care service for patients with long-term illness saves \$100 per patient by reducing hospital stay and costs of patient care, Sidney Shindell, M.D., in charge of the home care pilot study at Gallinger Municipal Hospital, Washington, D.C., told a joint session with the conference of Health Council Work.

The home care unit was set up as an independent administrative unit at Gallinger Hospital which treats indigent patients in cooperation with the District of Columbia Department of Health and Hospitals. Its purpose, Dr. Shindell said, was to determine: the nature of the eligible patient population; the effect of home care in reducing hospital stay costs; and the extent to which the program conserved the total number of beds. By a random selection, 177 eligible patients were divided into a study group and a control group. The control group was observed to determine what happened to such individuals using existing community facilities. Dr.

Shindell made the following points in his report.

Potential Is 2.1 Percent

During the study, approximately 7,500 patients were admitted to Gallinger Hospital. Of this total, 5.5 percent were medically qualified for home care service, but two-thirds of these were disqualified because of inadequacies in the home situation. This is equivalent to a home care potential of but 2.1 percent of all admissions.

The home care patients averaged 17.2 days stay in the hospital, 24 days less than the patients in the control group. They received 118 days of home care. The cost of hospital care was approximately \$13.50 per day and of home care, \$3.70. Significant savings to the community accrued during the 24 days of home service; but the costs of the two groups paralleled each other upon the discharge of the control patient to his home with out-patient care.

Hospital beds made available by the use of home care service totaled 10 or an equivalent of 1.9 percent annual increase in available beds. The savings in bed availability, like the savings in cost of care to the community, would be increased if a larger proportion of medically suitable patients had adequate homes or if domiciliary facilities were available.

Experience With Home Care In Four Large Cities

Planned medical care at home offers striking promises of economy of operation and satisfaction for patients and relieves pressures on hospital occupancy, but many problems remain—particularly those involving the financing of services for the medically indigent.

These were among the main points presented before a joint session of the health officers, medical care, and public health nursing sections of the APHA, with the Conference for Health Council Work.

Boston's Voluntary Plan Has Financing Problem

Financing medical care for the medically indigent remains an unsolved problem for a voluntary project, Henry J. Bakst, M.D., indicated in a discussion of a home care pro-

gram that meets the dual purpose of serving the needy and providing a vehicle for medical education.

Dr. Bakst, professor of preventive medicine at the Boston University School of Medicine and director of home medical and out-patient services for the Massachusetts Memorial Hospitals, based his observations

largely upon the long experience of the two institutions. A home care program for the needy and medically needy has been a joint activity since 1875.

Public relief agencies financed by Federal, State, and local funds help the totally needy meet the cost of medical care, Dr. Bakst explained. But this group, he said, makes up only one-third of the annual patient load of the Boston home medical service, about 35 percent of the 15,173 home calls made in the 12 months from April 1950 to March 1951.

The Medically Needy

Two-thirds of the visits are made to the medically needy—persons who are able to provide for ordinary day-to-day needs but cannot meet medical costs, he said. Usually, nonofficial agencies, such as the hospital volunteering the service, must subsidize the medical care for this group, he stated.

physicians or full-time physicians employed especially for visiting home care cases, have taken their place.

In spite of these difficulties Dr. Kogel feels that the "home care idea has given us in the Department of Hospitals a breathing space until modernization and replacement programs are completed and it has made a permanent place for itself in the scheme of hospital operation."

of filling immediate and direct patient needs. However, it proved to be excellent for teaching medical students, and made information about follow-up of cancer patients available to the tumor clinic staff teachers, Dr. Pfeiffer and Dr. Lemon reported.

The daily case load ranged from 1 to 11 patients, usually varying from 7 to 11; visits totaled 439, an average of 8 per patient before

death, hospitalization, or other disposition. Indigency varied from absolute, in terms of public assistance and hospital ratings, to partial financial lack. Occasionally a staff specialist referred a patient who was a suitable subject for teaching purposes. Ages of the patients were 21 to 90 years; average, 61 years; 84 percent over 50. Most women were between 50 and 61; the men between 60 and 70.

Terminal Cancer Patients Receive Home Care

Home care of indigent terminal cancer patients over a 2-year period made 676 hospital days available to persons with acute illness or chronic disease necessitating hospitalization, and saved the hospital \$12,000 as well.

These results of a study at the Hospital of the Woman's College of Pennsylvania, Philadelphia, to determine the feasibility and value of providing medical care for terminal cancer patients who could be cared for at home as well as, or better than, in a hospital bed were reported by Mildred C. J. Pfeiffer, M.D., M.P.H., director of the division of adult cardiovascular diseases, Pennsylvania Department of Health, and former director of the department of oncology of the Woman's College of Pennsylvania, and Eloise M. Lemon, M.D., fellow in oncology and clinical assistant in medicine at the college.

The need to continue the hospital's responsibility for medical management of indigent cancer patients was recognized by the Woman's Medical College shortly after establishment of a tumor clinic in September 1948, the physicians said.

Case Load

The medical social worker and the physician cooperated closely in selecting patients for the study, which was originally conceived as a method

Cancer Control Projects And Research Activities

That progress against cancer—in terms of control if not direct prevention—is possible was suggested in reports of current activities from Puerto Rico, Connecticut, and Massachusetts. At the same sessions of the Public Health Cancer Association and the epidemiology section, new data were presented on socioeconomic aspects, cancer detection, medical teaching, and the role of heredity.

90% of Cancer Patients Served in Puerto Rico

At least 90 percent of the cancer patients in Puerto Rico now receive diagnosis, treatment, or follow-up care through a cancer control pro-

gram of the Puerto Rican Government, reported Lyndon E. Lee, Jr., M.D., Roberto Fuentes, B.A., and Luisa Lefebvre, B.S., from the Puerto Rico Department of Health and the University. They predicted that a contemplated broadening of the program will insure the provi-

a half century
of progress →

public
health
nursing

sion of governmental aid to all cancer cases.

The cancer program was initiated in October 1949 when it became evident that the increasing public health problem of cancer among Puerto Ricans required an organized official control effort, the speaker stated.

Case Reporting

A statistical registry was established for the recording and analysis of pertinent data from all cancer cases in 72 hospitals. All physicians and hospitals were required by law to report to the Bureau of Cancer Control the details of any case diagnosed as cancer. Now pending are amendments to the law to require such reports from diagnostic and clinical laboratories, they said.

In considering immediately practicable steps to be taken, it was found that Puerto Rico's major difficulty in cancer service was a lack of personnel and facilities for microscopic examination of tissue. Consequently, an expert pathologist was retained to review and recommend solutions for the pathology problem, and additional equipment was provided for the broader functioning of a central pathology laboratory. It was noted that facilities for X-ray diagnosis and therapy also were increased and improved.

Cytology Center

Upon discovery that cancer of the cervix was the most frequently encountered condition, an intensified effort for early diagnosis of this type of cancer was promoted and a cytology center established. The initiation of a cooperative case-finding program for lung cancer produced gratifying results, they noted.

Educational aspects of the program, the Puerto Rican group reported, included distribution of a cancer manual to general practitioners and, in order to obtain uniformity in reporting, a "Manual of Tumor Nomenclature and Coding" to pathologists and hospitals. Weekly

tumor conferences for physicians were held at three major cancer centers and 10-week postgraduate courses, including lectures, clinics and operative demonstrations, were presented weekly in seven local areas by an itinerant instructor. Lectures also were given to ancillary medical groups and to lay organizations with mass education facilities.

At present, they continued, \$75,000 in service contracts for cancer diagnosis and treatment is allotted each year to two hospitals which care for 50 percent of Puerto Rico's cancer patients and an additional \$25,000 a year is divided among 11 other hospitals through a merit system of referral. This had made approximately 1,000 hospital beds available for cancer patients, but it was emphasized that such measures should be considered only as necessary, temporary expedients. They recommended construction in Puerto Rico of a central, government-supported cancer institute, devoted exclusively to the diagnosis and treatment of cancer patients and the investigation and teaching of all aspects of cancer.

Massachusetts Studying 24-Year Cancer Effort

The Massachusetts Department of Public Health has reappraised its cancer control program in a new series of studies on the effects of present day cancer control methods, reported Herbert L. Lombard, M.D., M.P.H., director of its Division of Cancer and Other Chronic Diseases. Cooperating in the study were Barbara Bennett, A.B., Barbara J. Drake, A.B., and Margaret E. Quinn, B.S., assistant biometricians.

The method of calculations and presentation of statistics on therapy used were the recommendations of the subcommittee of the World Health Organization. Records analyzed were those of 4,291 females with breast cancer who attended the

Massachusetts cancer clinics during 1927-50. Cases were classified in age groups, according to site of cancer originally diagnosed, and according to diagnosed or microscopically verified cancer. Dr. Lombard explained. From these data, tables and charts were prepared in all of the classifications for the computed rates of life expectancy for breast cancer admissions and for crude survival. Time period comparisons were made.

Survival Rate

In highlighting some of the findings, Dr. Lombard pointed out that the age-adjusted survival rate, corrected for deaths from causes other than breast cancer, probably gives one of the most representative pictures of the situation. The over-70 age group showed the greatest increase for the 5-, 10-, and 15-year survival periods; credit for this improvement is given to radical operations and better pre- and postoperative treatment. In earlier years, elderly persons with cancer were not usually treated by radical operation; now operations on 80-year-olds are not unusual.

The under 50 years of age group showed the highest percentage of cures as well as a larger percentage of highly malignant tumors. The high percentage of cures may be because the young have profited by their receptiveness to the educational programs in Massachusetts, he said.

Trends in breast cancer survival are upward, concluded Dr. Lombard, but further study is needed to determine all of the causative factors.

Patient, Physician Aided By State Cancer Register

A State-wide cancer record register is of practical value to the medical profession, the individual patient, and the community, as well as the public health worker, experience in Connecticut shows.

These benefits, all intermeshing, were discussed by Matthew H. Griswold, M.D., chief, and Earl S. Pollock, M.A., research statistician, division of cancer and other chronic diseases, Connecticut State Department of Health, before the Public Health Cancer Association.

The register, maintained by the State health department since 1935, contains histories of some 55,000 cancer patients treated in 31 of 86 general hospitals in the State, they reported.

Health Workers

From these histories the medical profession gets information on the extent of the cancer problem, the trends of cancer incidence and prevalence, methods of diagnosis, treatment and results, and survival time, the Connecticut officials indicated. The register also provides a starting point for special clinical investigations, which, in addition to providing valuable information, stimulate interest among the medical profession in evaluating the results of their work with cancer and also tend to improve reporting, they said.

Patients

The patient, in turn, benefits through better care as knowledge and interest in cancer increases, the officials indicated. But more directly, they said, the periodic follow-up system conducted as an integral part of the register assures the patient of adequate attention after treatment. The private patient is followed through the attending physician; the service case, by the tumor clinic. The information obtained for each case is recorded in the local register and forwarded upon request to the central register.

Research

The register is now being used in a study of environmental carcinogens, the officials reported. The records make it possible to select individuals who may have been exposed to carcinogens and to obtain

details of their various occupations. Analysis of the data should point toward specific hazards in specific industries as areas for further investigation, they pointed out.

Socioeconomic Factors In Female Cancer

A correlation between low socioeconomic status and cancer of the stomach was found for women, but not for men, implicating cultural factors as a cause, Edward M. Cohart, M.D., of the Department of Public Health, Yale University, said in reporting on part of a study conducted in New Haven.

The study was undertaken to determine if there was a correlation between cancer sites and socioeconomic status in the United States, as had been found in England and Denmark. A second phase of the study will attempt to trace the biologic factors responsible for the correlation, he said.

Records of 347 cases of stomach cancer in men and 263 cases in women between 1935 and 1948 in New Haven were obtained from the Cancer Register of the Connecticut State Department of Health, supplemented by death certificates. The cases were grouped in seven socioeconomic divisions and, more

broadly, in three socioeconomic regions, he explained.

A highly significant excess of observed to expected cases was found among women in the lowest of the three groups. No socioeconomic correlation was evident for men on this basis, Dr. Cohart asserted.

Better Cancer Teaching In Medical Schools

Most medical schools in the country have subscribed to a program of improved cancer teaching, Murray M. Copeland, M.D., director of the oncology department at Georgetown University Medical Center, Washington, D. C., told the Public Health Cancer Association.

The program of coordinated cancer teaching, recommended by the National Advisory Cancer Council, is based on the premise that the family physician is the pivotal figure in cancer control because he has the first opportunity to discover cancer, Dr. Copeland reported. Medical educators have agreed that medical training should offer every physician better opportunity to understand the cancer problem by instruction in early detection and treatment, he said.

Dr. Copeland called attention to the disparity between the proven

good results cancer treatment can give and the less satisfactory cancer statistics actually obtained.

The work of local and national organizations has apparently stimulated more people to recognize cancer symptoms and to seek aid early, he said, with reference to the studies of the Memorial Hospital of New York City on cancer diagnosis delays. The 1946 data showed that in 32 percent of the cases, patients were responsible for delay in diagnosis; in 1923-30 this figure was 44.3 percent. In 1946 the physician was responsible for 27.8 percent of delayed diagnosis, in contrast to 17 percent in 1923-30.

Credits Coordinator

Dr. Copeland credited the "cancer coordinator" with being the one common denominator in the various medical school programs and for gaining for cancer instruction an improved place in curriculums. One main objective, he noted, has been to give students a comprehensive concept of neoplastic diseases by integrating cancer instruction in the general curriculum.

The cancer coordinator has stimulated the internist, surgeon, pathologist, and radiologist to participate in cancer teaching, usually through advisory cancer committees, Dr. Copeland said. He has broadened the concept of cancer as a disease worthy of special attention, urging its distinct, but not necessarily separate, identification, as a public health, therapeutic, and research problem.

The cancer coordinator has also influenced many schools to achieve better cancer facilities and services, he said. Twenty schools had started tumor clinics, and 39 additional schools had expanded or improved their cancer clinics in 1950. Many have enlarged on visual education materials, record systems, and follow-up services. And 31 schools have undertaken clinical research, bringing the departments of medicine more actively into the cancer teaching program, Dr. Copeland concluded.

Cancer Detection Service Aids Preventive Medicine

In fulfilling its main objective of finding cancer cases, a cancer detection center otherwise serves the cause of preventive medicine by discovering many other pathological conditions and referring them for treatment.

Emerson Day, M.D., Thomas G. Rigney, M.D., and Dorothy Fahs Beck, Ph.D., of the department of public health and preventive medicine, Cornell University Medical College, drew this conclusion from analysis of 2,111 initial examinations of adults at the Kips Bay-Yorkville Cancer Detection Center.

The project was set up by the Cornell Medical College and the New York City Department of Health to study the role of cancer detection in adult health services and preventive medicine.

The findings revealed that 27 of the 2,111 examinees had cancer even though the group had been pre-screened to exclude persons with symptoms suggesting malignancy. More than half of the 27 had no symptoms, and were "true detections."

Precaution Rewards

Precancerous neoplasms and other lesions requiring care as a precaution against cancer contributed an average of 14.3 diagnoses for each hundred examinees. Polyps of the colon and rectum constituted the largest component of the precancerous group.

The other pathological conditions found in a presumably well group were about nine times as numerous as cancer and precancerous lesions, and 65 per hundred of these required medical care.

Diagnosis of all types of conditions totaled 3,094, or an average of 1.5 per examinee. Of these, 66 percent were not previously known to the patient. Forty-seven percent of all examinees were referred for

medical care. Four out of five referrals were to private physicians.

Diagnoses Requested

Younger age groups sought the center's services more than did the older, but the latter produced more diagnoses of all types.

The investigators concluded that a cancer detection service diagnoses a small but individually important number of asymptomatic cancer cases and supplies the impetus for the study and treatment of conditions assumed to be precancerous. It detects many other conditions needing attention and initiates corrective measures and early treatment by referral of all types of conditions for medical care.

Suspect Hereditary Factors In Breast Cancer

Common hereditary factors rather than a common environment would be the logical explanation of the fact that breast cancer occurs approximately three times as often in relatives of persons who have had breast cancer than in relatives of those whose family history shows no mammary cancer, Madge T. Macklin, M.D., research associate and lecturer in medicine, Department of Medicine, Ohio State University, told the Public Health Cancer Association.

This does not mean that a woman will have breast cancer because her mother or sister had it, Dr. Macklin went on, but if she does develop the disease it is more likely to be in the breast than in any other organ.

A group of 272 women with breast cancer was interviewed, Dr. Macklin reported, to bring about data leading to these indications. Control groups included 200 women who matched age for age the cancer patients, and a group of 180 patients with cancer other than breast cancer. The study analyzed data obtained from familial histories, correspondence from living relatives, and death certificates and hospital records.

Laboratory and Epidemiological Reports From Overseas

Reports from laboratory investigators and epidemiologists from widely separated areas of the world—Korea, Australia, Costa Rica, Egypt—brought to the APHA meetings observations and data on a variety of diseases infrequently noted in the United States but always potential threats, directly or indirectly.

Salmonella and Shigella Cause Epidemic in Korea

In Korea for the first 5 months of 1951, *Shigella* and *Salmonella* infections were epidemic among the critically ill, starved, and wounded prisoners captured by United Nations forces late in 1950.

Lt. Col. Lorenz E. Zimmerman, MC, USA, Armed Forces Institute of Pathology, Washington, D. C., who was with the 8217th Mobile Laboratory in Pusan at that time, said *Salmonella* infections produced a larger variety of clinical manifestations, and *S. paratyphi* was the predominating *Salmonella* type. Two dramatic manifestations of salmonellosis believed to be rarely, if ever, encountered in the United States were reported by Dr. Zimmerman.

Paratyphoid Ulcers

The first—acute perforation of an ileal ulcer and absence of significant bleeding among patients with paratyphoid fever—occurred in epidemic proportion. Surgical exploration was performed on over 200 patients because of signs of peritonitis incident to intestinal perforation. *S. paratyphi* were consistently recovered in the culture studies that were possible, he said.

Dr. Zimmerman attributed the low incidence of positive results partly to the unavailability of many surgical specimens until 36 hours after operation. He found the paratyphoid ulcers to have certain distinct ileal, bacteriological, and anatomic differences from typhoid ulcers. He continued with the following observations:

Many patients were symptomatic and ambulatory or only mildly ill until the time of perforation. Of 98 with known duration of illness before perforation, only 31 had been sick for more than 6 days. About one-half had denied illness preceding perforation, a striking contrast to perforation of a typhoid ulcer, which usually occurs during the second or third week of illness. Massive gastrointestinal hemorrhage—the complication most feared in typhoid fever—was conspicuously absent. No instance of hemorrhage was found in over 30 autopsies on patients dying of peritonitis or of other manifestations of *Salmonella* infection.

Preliminary investigation established that the perforating paraty-

phoid ulcers, like typhoid ulcers, occurred in the lower ileum—73 percent within 30 cm. of the ileocecal valve. Multiple ulcers were more common than single ulcers. On gross examination, paratyphoid ulcers were distinctive and could be differentiated from those of typhoid fever. They were ovoid, usually narrow, often slit-like, and lay transversely between folds of mucous membrane on the antimesenteric border of the ileum. Some were shallow, involving only the surface mucosa, while others penetrated deeply, causing perforation. They were often more easily located by exploration for evidence of peritoneal action.

Salmonella Septicemia

The other unexpected clinical manifestation of especial epidemiological significance was demonstrated in the cases of two patients who, though treated successfully for relapsing fever with meparsen, succumbed to a concurrent *Salmonella enteritidis* septicemia. *Borrelia* could not be demonstrated, but *S. enteritidis* was recovered, on autopsy, from the blood, urine, bile, and spleen of the first, and from the blood and spleen of the second. The second case also revealed an acute bacterial endocarditis.

In the great European epidemic of 1920-22, mortality rates from *Salmonella* septicemia in relapsing fever

municipal sanitation

a half century
of progress →

reached 63 percent. Abscesses, gangrene, chondritis, osteomyelitis, arthritis, and thrombophlebitis occurred in as high as 13.8 percent of the typhus and 3.4 percent of the relapsing fever cases. The 1937 findings of P. Y. Liu, S. H. Zia, and H. L. Chung showed that body lice obtained from patients indicated that *Salmonella* infection should be added to the list of louse-borne diseases.

It is important, Dr. Zimmerman felt, that the clinician recognize the therapeutic implications of the two concurrent infections since experience in Korea has shown chloramphenicol to be of value in both *Salmonella* and *Borrelia* infections.

By May 1951, most prisoners had been taught the basic elements of sanitary discipline; the malnourished had been well fed; and the wounded were recovering. These factors, combined with many others, brought the once serious epidemic under control.

Infect Australian Rabbits With Myxoma Virus

"In October 1951 I spent a night in a country hotel in northern Victoria and was intrigued to read a notice in the bar: 'An officer of the Lands Department will attend at the stockyards on Tuesday next to inoculate rabbits with myxomatosis. Landowners should bring 10-20 live rabbits.' That sort of thing went on over most of Australia," Sir F. MacFarlane Burnet, M.D., director of the Walter and Eliza Hall Institute of Research, Royal Melbourne Hospital in Victoria, Australia, told APHA epidemiologists.

Sir MacFarlane outlined the rabbit's significance to Australia before telling the epidemiology story of the dissemination of myxomatosis virus to effect biological control of the animal.

"Our rabbit is the European species that is found wild in England and is the ancestor of all the breeds of laboratory rabbits," he said. In-

troduced by homesick colonists around 1860, it spread from Victoria and New South Wales until rabbit colonization of the land was completed about 1930. Between 1 and 3 billion rabbits flourish in all the settled country below the tropics, spreading to arid areas according to seasonal conditions. Ten rabbits consume as much pasture as one sheep—a conservative estimate.

Elimination a Necessity

"The elimination of the rabbit would be by far the most effective single step to increase food and wool production," he stressed. The rabbit destroys natural vegetation in the marginal zone, causing wind erosion and sand drift. Once rabbits were recognized as serious pests, rewards were open for ways of exterminating them.

The Australian physician mentioned Pasteur's interest in the 1880's when the latter sent one of his men to Australia with *Pasteurella* cultures, but owing to the understandable skepticism of government officials he was not allowed to liberate the cultures. The possible use of myxoma virus was mentioned at various times, Sir MacFarlane said, and the first objective experiments dealing with Australian rabbits began in England in 1934. Investigations were moved to Australia when it became apparent that myxomatosis had no significant power to infect any other common animal.

It took 15 years more before the virus was effectively liberated, he said, because of "the rather illogical aversion of health authorities to allow field studies of the virus in any but sparsely populated areas, and the failure to grasp the importance of mosquito vectors for the spread of the disease."

Mosquitoes Are Vectors

In prewar field tests, one on an island off the South Australian coast, another in a dry inland area, he reported, "mosquitoes were inconspicuous or absent, and only a very

limited spread of the virus occurred."

When experiments were resumed in 1950, tests were made in higher rainfall zones in eastern Australia. Infection was mainly by contact, it was believed. Tests were made in the autumn, winter, and spring, but only a few local infections were observed.

Uncertainty existed as to how the virus spread in nature. The Australians had missed Aragno's work in 1942 on the natural history of myxomatosis in Brazil, and the realization that effective spread in Australia needed mosquito carriage came as a surprise.

In November 1950, Sir MacFarlane continued, the testing team was prepared to report a fruitless experiment. Then, word came in early December that rabbits were dying by hundreds along the Murray River flats near Balldale, where the liberations had been made. "This was front-page news for Australia, and everyone in the country was on the lookout for sick rabbits." The disease spread rapidly across New South Wales, reaching southern Queensland in 3 to 4 months—by the end of the Australian summer.

Evidence pointed to *Culex annulirostris* as the important vector. According to Sir MacFarlane, this very common mosquito breeds in shallow water at the edges of streams and in temporarily flooded regions. "It has a restricted flight range," he explained, "rarely moving as far as half a mile from its breeding place. The cross-country leaps of a thousand miles in 3 months could not have been due to this species, and there are a number of rival hypotheses to account for it—*Aedes theobaldi*, wind, human transport of mosquitoes in vehicles of one sort or another."

Inoculations

Commenting on the artificial dissemination of the virus, Sir MacFarlane said: "It is hard to be sure that the inoculations made any significant difference to the result."

The following summer, one with normal rainfall, saw the development of *Anopheles annulipes* as another important vector.

The virus investigations of Frank John Fenner, M.D., and his Melbourne colleagues may have general epidemiological significance, the speaker said. Studies show that myxomatosis is a member of the pox virus group. Field observations confirmed that vectors of myxomatosis need not be specific. The mosquito becomes infective for rabbits only by feeding through myxomatous lesions of the skin, resulting in mechanical contamination of the insect's mouth parts, and transfer to other rabbits is through a local lesion in the skin, not by injection of infected saliva into the blood. Any biting or sucking arthropod which feeds through the skin should serve. The role of the mosquito is merely that of a "flying pin," a phrase coined when Dr. Fenner discovered he could closely parallel his findings with mosquitoes by using an entomological pin pricked with a myxoma lesion.

"In myxomatosis, now by human action enzootic among Australian rabbits, we have a unique opportunity to watch a 'new' disease," Sir MacFarlane concluded. "I shall be surprised if the results do not eventually help us greatly in understanding some aspects of the past and present behavior of infectious disease in man."

Antibody Patterns Higher In Egypt Than Miami

Most Egyptian natives develop poliomyelitis antibodies in infancy and early childhood in contrast to the much slower and later antibody development found in Miami, Fla., residents.

This geographic and socioeconomic antibody pattern, possibly attributable to differences in living conditions, were reported by S. J. Liao, M.D., J. L. Melnick, Ph.D., and

J. R. Paul, M.D., of the section of preventive medicine, Yale University School of Medicine.

More than 60 percent of the infants tested in Cairo, Egypt, showed evidence of maternal antibody in the first 6 months of life, the investigators found. They lost this evidence of immunity during the second 6 months and reacquired it at the age of about 18 months. By age 5 most Cairo children had appreciable amounts of antibody.

Similar Patterns Found

A similar antibody pattern for poliomyelitis was found in the other crowded and low sanitation areas of Havana, Cuba, and the Latin-American areas in the Lower Rio Grande Valley of Texas, the investigators reported.

Serologic tests on Miami residents presented a different picture, they said. While about 40 percent of the newborn infants tested had poliomyelitis antibody, only 10 percent had reacquired the antibody at ages 5 to 9 years. The increase was slow: 50 percent had developed antibody at 5 to 9 years, and more than 80 percent in their 20's.

A child of 2 years in Cairo has an antibody development equivalent to that of a 15-year-old in Miami, the investigators stated.

They reported less marked differ-

ence in the Cairo and Miami antibody pattern for mumps. In both populations the proportion of persons with positive complement fixation tests rose rather slowly in the younger age groups. And in both areas, only 75 percent of the adult population was positive. This level of immunity to mumps was reached by 10 years of age in Cairo and by 15 years in Miami, they said.

Epidemic Hemorrhagic Fever Studied by Army

Epidemic hemorrhagic fever was first experienced by Americans last year in Korea, where it is now under intensive Army study, commented Joseph E. Smadel, M.D., chief of the department of virus and rickettsial diseases, Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D. C.

A "place" disease—not a contagious disease—and unknown to Korea prior to this time, epidemic hemorrhagic fever was the subject of Japanese and Russian studies in Manchuria and Siberia during the last two decades, Dr. Smadel said in reviewing the etiology and epidemiology of the disease.

"There were approximately 1,000 cases of this disease during 1951 and about 700 cases since then. Such

the attack on nutritional diseases

a half century
of progress →

an incidence of a serious disease always constitutes an important military problem," he stated.

Dr. Smadel reviewed the information on the disease which has been accumulated in a brief time. He described the epidemic area in Korea as a belt extending across the peninsula from Seoul to the present main line of resistance, with sharply defined foci in rural areas. "Most cases occur as isolated events, but small outbreaks are encountered which appear to result from almost simultaneous infection of the members of the group," he said.

Etiological Agent

According to Dr. Smadel, both the Japanese and Russian scientists believed that the etiological agent was maintained in nature through a cycle involving rodents and arthropods, but the two groups were inclined to incriminate different rodents and different arthropods.

The American studies during the past summer produced similar opinions regarding rodents and arthropods. Their findings, however, pointed to trombiculid mites as the likely vectors, he said, adding that this general group of mites provides the vector for scrub typhus, another classic example of a "place" disease.

Dr. Smadel emphasized that definitive information on the mode of transmitting epidemic hemorrhagic fever to man and the natural cycle of the disease in rodents and arthropods will not be obtained until the agent can be readily handled in the laboratory and used in crucial tests.

There are many lines of investigation which hinge upon the theoretically simple procedure of finding a suitable laboratory host for the agent, he said. Both the Russian and Japanese researchers demonstrated that the disease agent was filterable and could be transmitted from man to man by inoculation of body fluids obtained during the first few days of the febrile illness, but were not able to establish and maintain the agent in a common laboratory animal.

"Since the disease was first encountered among United Nations troops, extensive and laborious efforts have been made to find the answer to the crucial question of a suitable laboratory host," Dr. Smadel reported, adding that as yet these efforts were not successful.

Wild Birds May Carry Encephalitis Virus

The hypothesis that the appearance of the encephalitis virus in temperate regions during the summer may be due to bird migrations, was presented by Sir F. MacFarlane Burnet, M.D., of the Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia.

In discussing Murray Valley encephalitis, the speaker compared four severe epidemics which occurred in Australia during the years 1917, 1918, 1925, and 1951. He said studies indicate that the epidemics occurring in Australia differ only in detail from the epidemics of Kern County, Calif., and Yakima, Wash.

"What I have in mind is the possibility that persistence of these viruses in nature is confined to tropical or near tropical areas where mosquitoes capable of transmitting the virus are present all year," he said. Then, he depicted a bird in the stage of transient viraemia moving toward a temperate region, being bitten by and thus infecting several mosquitoes, which a week later infect another migrating susceptible bird. The second bird, continuing its flight, develops viraemia a hundred miles further away from the tropic and initiates another focus of infected mosquitoes. The presence of nesting birds in any locality so infected would soon build up a high infective potential.

"This is at present speculation, but it does provide a working hypothesis to account for the main features of the disease as seen in Australia, and just possibly, it may be

equally applicable to conditions in other parts of the world," Dr. Burnet said.

Serologic Survey

The findings of an extensive serologic survey in the epidemic area of the Murray-Darling River Basin led to Sir MacFarlane's hypothesis. In the summer of 1951 a large proportion of the population, the horses, dogs, domestic fowl, and wild birds, particularly water birds, showed serologic evidence of encephalitis infection. In 1952, the virus had vanished from the area, the speaker said.

Conditions in the area did not permit the virus to survive over winter, Sir MacFarlane concluded. He surmised that encephalitis "is not endemic in the Murray Valley, but reaches it from some other region only when climatic and ecological conditions are appropriate."

The abnormally heavy rainfall over the subtropical headwaters of the Darling River that preceded each epidemic in the area supplied a possible clue to the differences in the seasonal variations of encephalitis in the regions further north since the infection is common in tropical Australia.

While it has not been proved that Murray Valley encephalitis is spread by mosquitoes, Sir MacFarlane said, circumstantial evidence implicates as the principal vector the *Culex annulirostris*, a river bottom mosquito that feeds freely on water birds and rabbits, and indicates that wild birds are the main vertebrate host of the MVE virus.

A Barrier Zone Required For Sylvan Yellow Fever

The only hope of arresting the progress of sylvan yellow fever in Central America is to establish a barrier zone with effective insecticides and adequate control studies in a small terrain funnel between the

present location of the disease and its future zones of activity. Whatever the results, "we shall have learned much more for having made the effort, but if no attempt is made to establish this barrier zone . . . the grim mechanism will continue to advance unchallenged . . . and we shall remain merely the spectators in a great drama of our era." So Col. Norman W. Elton, MC, USA, director of the board of health laboratory, Health Bureau, Canal Zone Government, Ancon, C. Z., reported.

Pattern of Progress

Continuing his reports made earlier this year (one of which was published in the May issue of *Public Health Reports*), Colonel Elton made the following points:

In Central America the current sylvan yellow fever wave will move steadily northward through Nicaragua and Honduras and then north and west.

To deal with the disease effectively and to prevent needless confusion, a concerted effort has been made to determine its progress pattern and to maintain close contact with its activity. The wave has progressed approximately 13 miles per month although this might increase to 100 miles, he said, and incompletely controlled epidemic centers remain active up to about 2 months.

Types of Barriers

Open, deforested country and regions of minimal precipitation are barriers to the spread of yellow fever. The continental divide is not in itself a natural barrier. It was effective in Panama, west of the Canal Zone, but in Costa Rica, although higher than in Panama, it has been crossed in two localities. Further study is needed of the significance of rain forest continuity across the divide, similarities and differences in rainfall on the two sides, migrant farmers, and the various species of *Haemagogus* mosquitoes other than *spegazzinii* falco, as well as other canopy mosquitoes, as possible vectors at higher altitudes.

Working Links Between Hospital, Private, State Laboratories

Relationships between State public health laboratories and private and hospital laboratories were variously described as consultation, reference, evaluation, regulation, stimulation during a panel discussion sponsored by the Conference of State and Provincial Public Health Laboratory Directors. Reports were heard from three State laboratories, a private laboratory, and a hospital laboratory.

State Interest Encourages Private Laboratories

State departments of health should supervise, evaluate, regulate, and stimulate the expansion of privately operated laboratories in order to promote laboratory services which are uniformly ethical, adequate, and accurate, declared Albert Dickman, Ph.D., director of the Dickman Laboratories in Philadelphia, in the panel discussion.

Because of rapid and continuing advances in the medical sciences, he continued, laboratory services and requirements are becoming increasingly technical and complex. As an example he cited the 125 determinations now commonly performed by various Pennsylvania laboratories.

In urging an integrated laboratory program which he felt would best serve the public interest, Dr. Dickman warned that delays in stabilizing the laboratory profession complicate an already serious situation and stressed the need for cooperation among three main laboratory groups.

Three Main Groups

First, the analytical-biochemical-biological laboratories, offering to the medical profession analytical services exclusively; second, the pathologist-directed clinico-pathological laboratories, handling customary requests and referrals from the analytical laboratories and offering to the medical profession additional consultation, interpretation and diagnosis; and third, the public health

serology and chemotherapy

vs.
VD

a half century
of progress →

and reference laboratories, offering services for the indigent, analytical procedures beyond the scope of the other laboratories, and dealing primarily with the laboratory aspects of communicable disease and broad public health problems.

Dr. Dickman felt that a clear differentiation of the analytical-biochemical-biological laboratories and the clinico-pathological laboratories would eliminate the obstructions which in the past have prevented a cooperative solution of many laboratory problems.

He said that during the first 10 months of State health department supervision and licensing of laboratories in Pennsylvania—exclusive of hospital, governmental, and physicians' laboratories—many of the laboratories enlarged their accommodations, others installed new and modern equipment, and many directors attended meetings specifically arranged for study, discussion, and demonstration of modern procedures. Also, many were stimulated to initiate their own periodic evaluations of their services in anticipation of those to follow from the State.

Dr. Dickman expressed the hope that eventually the State department of health laboratory can become an educational institution for all the laboratories of the State, training suitable personnel, providing proper evaluation of techniques, and assisting in obtaining materials and reagents of adequate purity and reliability.

Consultation, Reference, Evaluation in California

The working relationship between the State public health laboratory and local clinical laboratories in California has become one of consultation, reference, and evaluation, Howard L. Bodily, Ph.D., acting chief of the division of laboratories, California Department of Public Health, told the Conference of State

and Provincial Public Health Laboratory Directors.

This relationship began in 1927, he said, when laboratory technicians began a voluntary certification program in cooperation with the State health department. The clinical laboratory law, passed in 1938, provided for licensure of laboratory technicians and nonmedical laboratory directors, or technologists, he continued. It prohibited performance of laboratory tests by anyone except technicians, technologists, and physicians or surgeons licensed in California, and limited direction of laboratories to licensed technologists and California licensed physicians and surgeons.

The State board of health, through the division of laboratories of the health department and two advisory committees, administers this law. It was recently amended to require a permit to operate a laboratory, as well as approval of laboratories and schools which train technicians, Dr. Bodily stated.

In addition to the two major committees, special committees assist in determining the part to be taken by the State public health laboratory in Rh determination, and in blood bank and similar activities, he said.

Administrative Links "Making Us Friends"

The administrative relationship between the bureau of laboratories of the Pennsylvania Department of Health and the hospital and private laboratories has "made us acquainted" and the service relationship "is making us friends," C. J. Gentzkow, M.D., director of the bureau, told the panel.

The administrative relationship originates in the laws and in the regulations issued under them, such as the law requiring premarital and prenatal serologic tests for syphilis (STS), said Dr. Gentzkow. Applications of laboratories for approval are reviewed by the health depart-

ment and the Advisory Committee on Laboratory Procedures. If the application is approved, serum specimens are sent to the laboratory and its performance is evaluated from the results of the tests. Quality of performance is evaluated regularly.

The value of the relationship under this act is evidenced by the general improvement in performance of the STS in approved laboratories, Dr. Gentzkow reported. Failures to turn in a satisfactory performance have decreased from 23 percent in 1950 to 9 percent in 1952. "Our laboratories feel free to call on us for assistance at any time," he said.

The passage of the so-called Analytical-Biochemical-Biological Laboratory Act in 1951 brought about a new administrative relationship between State laboratories and "certain laboratories making examinations of materials originating in the human body," Dr. Gentzkow continued. The act makes provision for the department of health to investigate and inspect laboratories, to deny permits, and to revoke permits previously issued. "We are now getting acquainted with some 60-odd laboratories for the first time," Dr. Gentzkow reported. Contacts have been established which will lead to service-type relationships.

Service

The second relationship is one of mutual service, according to Dr. Gentzkow. The State laboratory works beyond the scope of local laboratories, and in turn can refer to the Communicable Disease Center and National Institutes of Health laboratories of the Public Health Service, as well as to the various departments of the University of Pennsylvania and its graduate school and to the Armed Forces Institute of Pathology.

Technical personnel from hospital and private laboratories are given refresher training for varying periods. Laboratory personnel from the entire State participated in one recent conference at the Pennsylvania State College, he said.

Laboratories throughout the State study reports of methodology advances and also carry on their own studies. "When improvements in techniques or new methods have been studied and prove worth while, they are made available to all our laboratories," said Dr. Gentzkow. Hospital and private laboratories in turn report anything new and promising that they may discover. "These service relationships . . . are growing. All of us are becoming increasingly aware of the fact . . . we are mutually interdependent."

Comparative Proficiency Ratings Use Suggested

State public health laboratories should function as reference laboratories for private and hospital laboratories, J. V. Irons, Sc.D., director of laboratories, Texas State Department of Health, told the conference of Laboratory Directors.

They provide services useful in the prevention, recognition, and control of communicable diseases of public health importance, he noted. Nearly all perform bacteriological and serologic tests; most offer sanitary bacteriology and chemistry services; but few offer extensive diagnostic services in either medical mycology or virology. They do not generally perform clinical laboratory tests, which are the primary concern of the private and hospital laboratories. There is a growing need, he said, for the State laboratories to add some clinical tests "to meet the challenge of chronic diseases and diseases of old age."

In addition, the State laboratories should provide opportunities for refresher or specialized training of qualified personnel from private and hospital laboratories. They can also inspire confidence in the work of the private and hospital laboratories by evaluation of their services. He recommended the use of comparative proficiency ratings to detect deficiencies.

Prevention of Poliomyelitis With Gamma Globulin and Vaccine

Two advances in the search for preventive measures against poliomyelitis were reported at the Cleveland APIA meeting. William McD. Hammon, M.D., Dr. P.H., professor of epidemiology of the University of Pittsburgh Graduate School of Public Health, gave preliminary results of mass gamma globulin trials. Howard A. Howe, M.D., adjunct professor of epidemiology at the Johns Hopkins University School of Hygiene and Public Health, reported on use of a killed virus vaccine in six children.

through the fifth week, at least, Dr. Hammon reported.

The tests took place during epidemic outbreaks in Provo, Utah (September 1951), and in Houston, Tex., and Sioux City, Iowa (July 1952). The gamma globulin was processed from blood collected during World War II by the American National Red Cross and contained in approximately equal amounts antibodies against Brunhilde, Lansing, and Leon types.

Preliminary findings based on clinical diagnoses were summarized by Dr. Hammon as follows:

" . . . 54,772 children between the ages of 1 and 11 years were inoculated, one-half of them with gamma globulin and one-half with a solution of gelatin. These three field tests were conducted in areas that were experiencing severe epidemics of poliomyelitis. The injections were given to apparently normal, healthy children living in the area, with the full understanding, permission, and cooperation of the parents. Which of the two materials any one child had received was unknown to all—

Report Marked Protection In Gamma Globulin Test

Field tests involving some 55,000 children in 3 epidemic areas indicate that injections of gamma globulin containing antibodies against the 3 known poliomyelitis viruses gave marked protection that lasted

children, parents, and investigators—until completion of a follow-up period considered to be adequate for determining a final diagnosis.

Protection Demonstrated

"A preliminary tabulation of results as of October 1, 1952, shows that paralytic poliomyelitis had been diagnosed in 90 cases in the study groups. Analysis of these patients on the basis of the type of injection received shows that significant protection was conferred by the gamma globulin. During the first week after injection there was no significant reduction in the number of cases in the group receiving gamma globulin, but the severity of paralysis appears to have been modified. From the second through the fifth weeks highly significant protection was demonstrated. After the fifth week this was less evident, but more definite conclusions regarding the duration of the protection and possible modification of disease should be available after a longer period of follow-up. Laboratory studies, still incomplete, should give information regarding the effect of gamma globulin on inapparent infection and the subsequent development of active immunity."

The report—from which the above is taken—was read before the epidemiology and laboratory sections on October 22. Together with two other papers, one giving the plan of controlled field tests and the results of the 1951 pilot study in Utah, and the other outlining the conduct and early follow-up of the 1952 Texas and Iowa-Nebraska studies, it was published in full in the *Journal of the American Medical Association* for October 25, 1952, pages 739-760.

In Trial Stage

Looking ahead, Dr. Hammon said that "if it is found that gamma globulin has not interfered with inapparent infection and the development of active immunity during the period of protection against clinical disease, this agent will have a wide field of usefulness, at least until a

more effective and equally safe means of prevention has been developed."

"The present supply of the blood fraction suitable for poliomyelitis prevention use is extremely limited and completely inadequate to meet expected needs," Dr. Hammon said. Since World War II, he pointed out, there has been a sharp decline in public blood donations. However, he noted, the most heartening aspect of the situation is the willingness of the public to cooperate in the solution of a public health problem, as demonstrated by their participation in the field trials.

Associated with Dr. Hammon in the conduct of the field studies and as co-authors of the reports were Dr. Lewis L. Coriell of the Camden (N. J.) Municipal Hospital, Dr. Paul F. Wehrle of the U. S. Public Health Service, Dr. Christian R. Klimt, fellow of the Rockefeller Foundation, and Dr. Joseph Stokes, Jr., of the Children's Hospital in Philadelphia and of the University of Pennsylvania. The work was supported by the National Foundation for Infantile Paralysis.

Six Children Respond To Polio Vaccine

A satisfactory antibody in humans to killed poliomyelitis virus was reported by Dr. Howe in an exhibit at the meeting. Tests of six children in Baltimore showed antibody levels to the Lansing, Leon, and Brunhilde viruses comparable to levels found in vaccinated laboratory chimpanzees.

The vaccine, prepared from formalin-treated virus, is the result of studies over nearly 10 years on monkeys and chimpanzees which have shown conclusively that it is possible to immunize the animals against all types of the disease even when they are "challenged" by injection of active virus directly into the brain.

The children tested were between 2 and 5 years of age. All are inmates of the Rosewood Training School, a Maryland state-operated institution for the mentally retarded. They were chosen for the study because of their isolation from most outside contacts and the fact that they could be kept under continuous observation. Five ward mates of the children under study were not vaccinated and served as controls.

Written permission was obtained from the parents or guardian of each child for the studies, which were conducted with the cooperation of physicians and officials of the Maryland Department of Mental Hygiene.

Although Dr. Howe expressed his satisfaction with the results of the tests, he cautioned that the vaccine used is experimental and that more extensive laboratory work would be necessary before an effective and practical vaccine could be made available for general use.

Many Unknowns

There are many "unknowns" still to be determined, he pointed out, and, undoubtedly, the present vaccine will undergo changes before it can be used on a large scale.

Such factors as exact amounts of antibody necessary to immunize, the length of time immunization levels remain effective, the elimination of substances in the vaccine which might cause side reactions, and new methods for growing the active virus on a large scale must be worked out in the laboratory, he declared.

The human immunization tests were made during the summer and fall of 1951. Blood samples from the six children were taken on June 26, 1951, and the first dose of vaccine administered by intramuscular injection the following day. Only a very small amount of vaccine was given. As an extra precaution, gamma globulin, a human blood derivative which provides a passive or short-term immunization and prevents paralysis by destroying active virus in the blood stream, was given at the same time.

Antibody Response

Fifteen weeks later a second and smaller "booster" injection of the vaccine was given. Blood tests to determine the antibody response were made at regular intervals over 6 months.

Response to the Lansing and Leon varieties of the disease was the highest, while that to the Brnkhilde strain was poor. Nevertheless, the reaction of two children to the latter type was definite and consistent with the responses to the other types. This same finding was recorded also in the tests on chimpanzees, and Dr. Howe expressed confidence that a larger quantity of the vaccine would produce higher levels of response.

At no time have any of the children shown any apparent discomfort or any untoward local reaction to the vaccine. The children will be followed closely for an indefinite period to determine how long detectable antibody will remain. The work was supported by the National Foundation for Infantile Paralysis.

Polio Follow-Up Program Revised in New York

Periodic evaluation of long-term follow-up of poliomyelitis patients—and for other similar programs—results in more efficient and more economical operations and frequently in radical changes in focus and procedures, reported Helen M. Wallace, M.D., director of the bureau for handicapped children, Patricia Heely, R.N., director of the bureau of nursing, and Herbert Rich, senior statistician, all of the New York City Department of Health; and Margaret A. Losty, R.N., director of nursing service for the National Foundation for Infantile Paralysis.

Follow-up Care Analysis

They made an analysis of the follow-up care given to 1,523 poliomyelitis patients during 1949 in New York City. The program studied

had been set up in the 1940's and provided for a 2-year period of home visiting by public health nurses. The plan represented an agreement of opinions of medical leaders in the field, members of the health department, and the voluntary nursing agencies.

Analysis of the plan as it operated in 1949 revealed:

1. The same amount of home nursing supervision was given to the nonparalytic, and the bulbar and other paralytic types of patients.
2. The same amount of home nursing supervision for the period of follow-up was given to all patients regardless of their medical status at 3 months after onset of illness.
3. 1,200 or 10 percent of the home visits were made after the patient had been discharged medically.
4. Fifty-two percent of the nonparalytic school age children who might have been followed through the school health service were not seen by that service.
5. Other examples of wasted home visits were the multiple visits made while the patient was hospitalized or away at school.
6. In only 4 percent of the patients a subsequent or new paralysis was detected; almost all of these patients were under continuous and competent medical care.
7. In one-half of the nonparalytic group subsequent paralysis was de-

tected within 3 months after onset; one-third of the paralytic group developed new paralysis within 1 year after onset.

8. One-half of the paralytic patients under private medical care did not receive such care from a qualified specialist.

9. There is some evidence that physical therapy was continued beyond the period when it is usually considered productive.

Wallace and her colleagues observed that "had the data obtained through this study been available in 1949, and the follow-up plan revised accordingly, approximately 8,350 of the 12,437 public health nursing visits actually made by health department nurses alone might have been saved and made available for other patients."

Priorities Set

Priorities, the authors felt, must be established, and they suggested that these "would logically seem to be: the nonbulbar paralytic group; the bulbar paralytic group; and the nonparalytic group. Patients who are homebound because of paralysis should receive high priority. Existing programs, such as the school health and child health services, should be used to their maximum for follow-up of patients, rather than superimposing another service."

the health department in field and laboratory

a half century
of progress →

As a result of this study, the follow-up program has been revised, Dr. Wallace reported. A guide for visiting has been set up. The number and frequency of home visits will be based on the needs of the patient and his family, and will be determined by the public health nurse in consultation with the patient's physician. The nurse, of course, may call upon her supervisor and consultants in the field for guidance. The suggested priorities are established, the New York group said, and included is the principle of use of existing school health and child health services. It is recommended that nonparalytic patients generally be visited for a 3-month period, and paralytic patients for 1 year.

Wallace and colleagues reviewed, also, problems of referral to special-

ists, interchange of information between hospitals and community nursing services, and physical therapy. They pointed out that while this study resulted in revisions, "it should not be taken for granted that this . . . is the final answer. Undoubtedly, periodic reevaluations will result in further modifications." They reported that a similar study is under way concerning follow-up of children with cardiac handicaps.

Polio and Rabies Viruses Show No Cross Immunity

Contrary to recent news reports that rabies vaccination may protect man from poliomyelitis are the recent findings of two scientists from the medical research institute connected with the Michael Reese Hos-

pital in Chicago. In a series of three experiments using 200 Swiss mice, no evidence of cross immunity was found between the poliomyelitis virus and the rabies virus by Albert Milzer, M.D., and Freddie Nicholson, B.S.

Dr. Milzer, chief of the microbiology department of the institute, reported that immune Lansing antiserum failed to neutralize the rabies virus, and hyperimmune rabies antiserum did not neutralize the Lansing virus. In every experiment the vaccine or hyperimmune serum tested showed significant protection against homologous virus.

The researchers warned that rabies virus has the possible hazard of producing allergic encephalomyelitis in vaccinated individuals and that its use should be restricted to proven indications.

New Methods and Approaches In Laboratory Techniques

Laboratory procedures have been made easier by the achievements of research bacteriologists in Baltimore, in the Public Health Service Communicable Disease Center, and in the Chemical Corps at Camp Detrick.

The laboratory section heard reports covering recent studies on the re-use of streptococcus cells, population changes in Brucella cultures, the virulence of Corynebacterium diphtheriae, and the use of Clostridium sporogenes to indicate sterility in laboratory instruments.

Virulence Induced in Avirulent Bacilli

Additional data on the effect of bacteriophage to virulence in *Corynebacterium diphtheriae* were reported by Elizabeth I. Parsons, Sc.D., bacteriologist, Communicable Disease Center, Public Health Service, and Martin Frobisher, Sc.D.,

head of the bacteriology department, University of Georgia.

Reviewing literature, they noted that several investigators have shown that toxigenic strains of *C. diphtheriae* from cultures of avirulent *C. diphtheriae* developed from contact or infection with specific bacteriophage, repudiating the earlier theory that avirulent strains never acquire virulence.

Findings

Following a description of methods and materials used at the Communicable Disease Center in studying this problem, they summarized the findings:

The activity of a given phage of some strains of diphtheria bacilli may be increased from 10 or 100 up to 10,000 or even 100,000.

Of 37 strains of avirulent *C. diphtheriae* so far tested, the change to virulence has been induced in only six, using six different bacteriophages for each culture.

Virulence may be induced in a given strain by one phage but not by another.

Although two phages specific for, and propagated continuously on, virulent, gravis-type *C. diphtheriae* have been among the six phages used in these studies, no avirulent gravis strain has acquired virulence as a result of phage action.

The change of virulence has so far been induced only in mitislike strains, in spite of as many as 50 culture-to-culture passages with some avirulent strains.

What appeared to be bacteria-free bacteriophage suspensions yielded typical virulence tests in rabbits. The reactions seemed to be due to toxin, but origin of the toxin is not clear.

New Washing Method Permits Cell Re-use

A procedure for reclaiming and reusing bacterial cells employed for adsorption of antibody in the production of streptococcus typing serums has been devised by Elaine L. Updyke, Sc.D., and Elizabeth Conroy, M.S., bacteriologists with the Communicable Disease Center, Public Health Service.

The large volumes of broth cultures that must be handled to obtain enough streptococcus cells for the adsorption process make it advantageous to use the same cells repeatedly, the bacteriologists explained.

The packed cells are reclaimed after use by suspension in 4 to 5 volumes of N/5 HCl in physiological saline and overnight refrigeration at 4° to 10° C. The acid-cell suspension is centrifuged and the cells washed three times in 4 to 5 volumes of physiological saline. The second saline suspension is adjusted to pH 7.0-7.2 with N/1 NaOH. Cells receiving this treatment have been satisfactory for as many as eight adsorptions, they reported.

Practical Technique

Resuspension of the tightly packed cells for the acid and saline washes is facilitated by a midget household electric mixer, the blade of which fits easily into a 50-ml. centrifuge tube. The mixer blade is transferred from tube to tube after a tap water rinse, and 20 specimens can be suspended in the time previously required for 1.

This technique, the bacteriologists said, has proved practical in routine use and was adopted without further study to ease the laboratory work-

load. It takes less time and labor than the growth and collection of fresh cells, even with a Sharpless centrifuge available, they found.

Other workers, they suggested, may want to investigate the procedure further—to study the efficacy of other concentrations of HCl, of other acids, of alkalies, or of high salt concentrations, and to determine the optimum time of all exposures to acid and the length of refrigeration. Possibly, they concluded this technique can be adapted to other bacterial antigen-antibody systems.

Better Procedures for Culture Recognition

A variety of environmental conditions capable of modifying metabolite production can affect population changes in *Brucella* cultures, both quantitatively and qualitatively, and better recognition of them can assist in improving routine laboratory procedures, asserted Werner Braun, Ph.D., and Robert J. Goodlow, Ph.D., of the Chemical Corps Biological Laboratories, Camp Detrick, Frederick, Md.

Pertinent Data

In reviewing the problem of stabilizing *Brucella* cultures, the bacteriologists stressed the recognition

of alanine and valine as two naturally produced amino acids which can selectively enhance the establishment of cells with different antigenicity, immunogenicity, and virulence. Pertinent *in vitro* data and their evaluated relationship to some problems of routine laboratory procedures were outlined as follows:

The degree of heterogeneity in heterogeneous cultures should be ascertained whenever possible and every effort made to start new cultures with a homogeneous inoculum. Colonial morphology is a helpful indicator of antigenicity and virulence.

Cultures should be incubated as briefly and transfers made as infrequently as possible since population changes are likely to occur during any period of growth.

Solid media are preferable to liquid media for maintaining stock cultures. The inhibitory effects of metabolites and the effects upon population changes are far less pronounced on solid media.

Transfers from single colonies of cells with the desired characteristics are preferable to mass transfers. Single colony isolates tend to promote the maintenance of homogeneous cultures since it is more likely that even a small proportion of mutant cells in the parent culture would be excluded in transfers from single colonies. Conversely, they might carry over such mutant cells,

the nurse's home visit and rural sanitation

a half century
of progress →

thus preserving existing heterogeneity by giving the cells opportunity for further establishment.

The recognition of the role of the substrate in the production of selectively inhibitory amino acids and the discovery that with alanine such inhibition can be overcome by adding pentothionate indicate that appropriate modifications of the medium can greatly reduce the opportunity for population changes.

Ultimate Goal

The bacteriologists concluded that the "ultimate goal for the isolation of *Brucella* from the bloodstream should be a method permitting direct cultivation onto solid media." They warned that alanine production is greatly enhanced in liquid media in the presence of immune serum, and that under such conditions population changes can occur rapidly which might cause erroneous identification of the type present *in vivo*.

Search Goes on for Agent Of Nonspecific Urethritis

Nonspecific urethritis and prostatitis could not be related causally to any particular microbial agent, concluded Capt. Bernard M. Wagner, MC, Capt. William H. Morse, MC, and Col. Dwight M. Kuhns, MC, members of the laboratory service and urology section, Walter Reed Army Medical Center, Washington, D. C.

Seeking to define an etiologic agent, to determine the role of pleuropneumonia-like organisms (PPLO), and to find the most satisfactory treatment method, the Army researchers studied nonspecific urethritis and prostatitis in 84 young males with a history of sexual exposure preceding the onset of acute conditions.

Increase in Korea

Nonspecific urethritis and prostatitis were observed in the last war but have increased since the Korean action, especially among servicemen

overseas, they reported. Although it was once thought that nonspecific urethritis resulted from inadequately treated gonorrhea, the Walter Reed studies indicated that only 32.1 percent of the patients had a gonorrhea history. Fifty-eight percent had received antimicrobial agents for acute urethritis—gonorrheal or nonspecific.

"By far, urethritis was the outstanding clinical picture," they reported. "However, 11 percent of the cases had signs and symptoms of a primary nonspecific prostatitis. In 29 percent, urethritis and prostatitis were present in equally severe form."

The study confirmed previous findings, they announced. "We were unable to demonstrate an agent or agents which could be considered as etiologic in the light of present knowledge. While human strains of PPLO may be found in an unpredictable number of cases, they cannot be implicated as causal agents at this time."

Terramycin Effective

They continued: "The almost constant parallel isolation of staphylococci with PPLO in our study and others raises the question as to whether the PPLO might not be L variants of the staphylococci." But the criteria for PPLO identification needs further investigation, they said.

No relationship was apparent between the type of organisms isolated and the ultimate effect of therapy, Capt. Wagner and his colleagues reported. Terramycin induced the most striking changes by effecting clinical response early and more completely than aureomycin plus a sharp and statistically significant reduction in the total relapses, they said. The simultaneous development of resistance to terramycin when organisms were resistant to aureomycin has been demonstrated, but it is not true that clinical failure with one means failure with the other, they said. The efficacy of terramycin observed in nonspecific urethritis suggests that the drug acts on susceptible agents relatively

resistant to aureomycin, but the exact mechanism of its action must remain speculative at this time, the researchers concluded.

Histoplasmosis Antigens Reported Isolated

The isolation of an antigen that apparently is more specific for histoplasmosis than the long-used histoplasmin which reacts with other mycotic infections was reported in a preliminary study by Charlotte C. Campbell, B.S., mycologist of the Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D.C.

This antigen, Miss Campbell said, is produced in abundance by the mycelial phase of *Histoplasma capsulatum* and reacts only with serums from histoplasma infections, but it does not detect very early complement-fixing antibody.

Another antigen isolated in the same study, is produced in greater quantity by the yeast phase of the organism and detects antibody in serums from very early cases of mild histoplasmosis. However, this antigen also reacts with serums from early cases of other mild mycotic infections.

Miss Campbell emphasized the importance of using the yeast phase antigen to detect primary histoplasmosis and use of the mycelial phase antigen to follow the serologic course of more severe cases of the disease.

Neutral Red Reaction Proves Valuable

A study of 168 freshly isolated acid-fast strains culturally consistent with *Mycobacterium tuberculosis* suggests that the neutral red test measures the virulence of mycobacteria as satisfactorily as the conventional inoculation of experimental laboratory animals.

The tests were evaluated by Maj. Warren C. Morse, MSC, Martha C.

Dail, and Lt. Irving Oltzky, MSC, in the bacteriology department of the Army Medical Service Graduate School, Walter Reed Army Medical Center, Washington, D. C., and in the Second Army Area Medical Laboratory, Ft. George G. Meade, Md.

Timesaver—Reduces Hazard

They found that the use of the neutral red reaction effects an appreciable saving of time in the laboratory diagnosis of tuberculosis, taking 2 hours as compared to the 3 to 4 weeks required for animal virulence studies. Furthermore, they found that the use of the neutral red reaction reduces the health hazard to laboratory personnel working with infected animals maintained for pathogenicity studies.

Index of Sterility Proves Reliable

Use of a heat-resistant, spore-forming organism as an indicator of the sterility of laboratory instruments—similar to the process canners use on experimental packs—was recommended by Harriette D. Vera, Ph.D., research bacteriologist of the Baltimore Biological Laboratory.

Dr. Vera suggested that a few units contaminated with an organism like *Clostridium sporogenes* and included with the other units to be sterilized would be a reliable index of sterility. "It is possible to test large numbers of units of unknown contamination and obtain no evidence of failure," she said.

Experiment Results

The results of a sterilization experiment on 75 test tubes of unknown contamination and 25 tubes deliberately contaminated with *C. sporogenes* were given as an example. The tubes, dried, stoppered, evacuated, and given a heat application of about 800° F. briefly at the base, were tested about 2 months after preparation.

No organisms were found on the 75 test tubes of unknown contamination. But *C. sporogenes* was recovered from 19 of the 25 contaminated tubes—proof that the sterilization was not sufficiently effective. None of the 75 tubes had been contaminated by chance by a resistant organism—but they might have been.

"If the contaminated control tubes had not been included in the test, the heating procedure would have seemed satisfactory, and the results would have given a false sense of security," stated Dr. Vera, pointing out that a process that kills *C. sporogenes* will assuredly kill the more common contaminants such as cocci or coliform organisms.

Isolation of *C. sporogenes* from rolls of dental cotton after they had been autoclaved at 121° C. for 15 to 30 minutes led to a series of tests and the use of the organism in the Baltimore laboratory as an indicator of sterilization efficiency. The cotton was being investigated for use as air filters on the needles of bleeding units.

Efficiency Indicator

A *Bacillus* could also be used as an indicator, Dr. Vera said. But a 5-day culture of *C. sporogenes* in dextrose-free thioglycollate broth ordinarily shows heavy spore production and is convenient for use in contaminating control units, she re-

ported. It can be washed through the lumen of hypodermic needles and tubing, and can be applied to cotton, glassware, and other articles. Contaminated units are preferably prepared weeks or months in advance, dried, stored, and used as needed.

Reports on Antigen Tests For Brucella Infection

Work on the laboratory confirmation of *Brucella* infection was reported by Nell Hirschberg, Ph.D., of the North Carolina State Laboratory of Hygiene, and Mary E. Yarbrough, Ph.D., of Meredith College at Raleigh.

Results of tests using dilute phenol extracted antigens of *Brucella*, adsorbed onto collodion and onto sheep erythrocytes, were described in detail. Time and temperature at which adsorption of the antigen takes place, are important factors in the results obtained, they said.

Long extraction and simple concentration by evaporation have not increased the reactivity after adsorption onto collodion. Both procedures result in extracts unsuitable for use with sheep cells, they commented. All antigens prepared by dilute phenol extraction show a very low carbohydrate content by the anthrone reaction.

The Tuberculosis Control Problem And Modern Therapy

The newer methods of treating tuberculosis, such as chemotherapy, excisional surgery, and vaccination, were viewed with tempered optimism at the special session on tuberculosis control. The results so far are promising, the conferees were told, but as yet there is neither a widely specific cure nor effective immunization. Tuberculosis, they were reminded, is by no means a disappearing disease.

Careful Evaluation Urged For Therapy Programs

The current world-wide drop in tuberculosis mortality is a phenomenon that is gratifying but not wholly explained, Esmond R. Long, M.D., director of medical research for the National Tuberculosis Association, and director of the Henry Phipps Institute, University of Pennsylvania, stated. Dr. Long believes the decrease in tuberculosis mortality rates should supply leads for extensive social and medical research.

Optimism of experts toward chemotherapy of tuberculosis, he declared, is justified by the enthusiastic and massive accumulation of data, but he urged further unbiased assessment of the results of different methods of administration of the drugs.

Other developments in tuberculosis treatment and control cited by Dr. Long were: (1) chest surgery to remove small infected segments of the lung; (2) advancement of methods to limit sources of contagion; (3) continuous and repeated chest surveys with X-ray; and (4) expanding BCG programs, particularly the

investigations relating to the methods of administration of this vaccine.

Interest in analytical evaluations of the BCG vaccination programs, which are being conducted by the Tuberculosis Research Office of the World Health Organization, was expressed by the speaker. Also he hoped that WHO will investigate the results of oral administration of BCG as practiced in Latin America.

Surgery and New Drugs Helping More Patients

Newer methods of therapy offer assurance of recovery and freedom from relapse to an increasing proportion of tuberculosis patients, Harold L. Israel, M.D., M.P.H., of the Graduate School of Medicine, University of Pennsylvania, stated. The last half dozen years have brought new advances in chemotherapy and excisional surgery, he continued, although prolonged bed rest is still necessary in treating tuberculosis.

"The objective of treatment is no longer merely to abolish symptoms or to render the patient noninfectious; the present aim is to excise, whenever possible, residual lesions that may be responsible for relapse," Dr. Israel said.

Chemotherapy is effective, "in small measure or great," in almost every case of tuberculosis, he stated. It often results in healing of minimal or moderately advanced tuberculosis and, in advanced cases, makes surgery possible.

Surgical Risk Small

In excisional surgery, Dr. Israel said, the surgical risk is "reasonably small." He added that, in the fu-

ture, surgery may be advised for small tuberculous infiltrations "as promptly as it is now advised for tumors." Surgery should be followed by a 6-month period of bed rest and chemotherapy to insure healing of the smaller residuals, he pointed out, urging that large scale, carefully controlled studies be made to determine the importance of bed rest, "the most costly and onerous factor in present day treatment."

Discharges against advice and case mortality rates have declined markedly in the last 15 years, the physician reported, largely because of the greater receptivity of patients to the newer methods of treatment.

The present aim is to go beyond inactivity of the disease as a criteria to eradication of any residuals large enough to cause relapse, Dr. Israel stated. If this is to be accomplished no immediate saving in time or money can be expected, he continued, but both will be well spent if observation confirms the growing belief that most tuberculous patients can be cured, rather than patched up.

Ohio County Coordinates Tuberculosis Control

Administration of tuberculosis control organizations in many metropolitan areas lags behind therapeutic advances, and, unfortunately, legislative attempts to cope with the problem have not always considered the epidemiology of the disease, reported Joseph B. Stocklen, M.D., Cuyahoga County, Ohio, tuberculosis controller; Dean Halliday, executive secretary of the Anti-Tuberculosis League of Cleveland and Cuyahoga County; and Harold J. Knapp, M.D., Cleveland's commissioner of health.

The three officials cited Ohio's situation as typical. Although control is a health department responsibility, the county government is obligated to finance hospitalization and the health department finances case finding and follow-up, making standardization of control impossible except by cooperative agreement.

Control coordination has been achieved in Cuyahoga County, Ohio, by naming the medical superintendent of the county tuberculosis hospital to the position of deputy health commissioner in each of the six health departments of the county, thus giving the health units continued control responsibility for case finding, hospitalization, and follow-up.

A Community Function

The superintendent directs control activities from a centrally located clinic in Cleveland rather than from the hospital. "We believe this is important," Dr. Stocklen and his colleagues stated, "since the personnel of the tuberculosis hospital, which often is isolated geographically, tend to develop an insular attitude," and, they added, control of tuberculosis is a community function, operating inefficiently if overemphasis is placed on any one phase of control. Tuberculosis clinics in the county are staffed by part- and full-time physicians who have had extensive experience in tuberculosis hospitals.

The Anti-Tuberculosis League leads in education program and has supported the official control program whenever needed, stimulating the development of the county-wide program which culminated in the creation of the position of county tuberculosis controller in 1943. It is believed that this interlocking program with official agencies is unique among large city voluntary tuberculosis agencies in the country, the three leaders remarked.

Chest X-ray surveys in the county have been continuous since 1943, and the percentage of tuberculosis cases found among persons X-rayed has decreased from 1.5 to .6 in 1949. From the 579 deaths and approximately 1,500 new cases reported in 1940, and 262 deaths and 2,165 new cases in 1951, it is obvious, they said, "that we grossly underestimated the number of cases of unknown tuberculosis existing in the general population in 1940." Many cases either

were not known or not reported, Dr. Stocklen and his associates pointed out.

Through the years, the many tuberculosis patients needing hospital care locally has been a serious obstacle in achieving adequate control, they continued. A new addition to the county tuberculosis hospital has added 200 beds to the 850 existing high standard beds, but with the current waiting list at 258, "the staffing of these beds now appears to be a problem of the greatest magnitude," they asserted.

New Emergency Treatment

They mentioned an emergency measure adopted in 1947 when patients with active tuberculosis were admitted to the hospital for 3 days during which pneumoperitoneum was instituted and in many cases phrenic nerve interruption employed. Patients then received pneumoperitoneum on an ambulatory basis, and now streptomycin and para-aminosalicylic acid are used with excellent results, they reported.

Follow-up of 14,000 cases on the registers is a problem for the nursing divisions. Cases include all degrees of activity. Dr. Stocklen and his associates said that they are "attempting to decide whether we should follow cases of minimal, inactive tuberculosis. There is no question but that a small number of

these cases do relapse. Whether the number is large enough to justify following them remains to be answered."

Tuberculosis Problem Remains Active

"Tuberculosis is by no means a disappearing disease in this country, whether mortality or morbidity is the measure," said Robert J. Anderson, M.D., chief, Division of Chronic Disease and Tuberculosis, Public Health Service.

According to the latest estimates of the National Tuberculosis Association and the Public Health Service, there are now 1,200,000 persons in this country with tuberculosis. A half million cases are known to health departments, and 250,000 of these are active cases. In addition, there are 700,000 unknown cases, of which 150,000 are believed to be active, he reported.

Pressing Shortages

Shortage of tuberculosis facilities and manpower, and problems of budget and staff are as pressing as any in public health, Dr. Anderson said. In connection with the Hill-Burton Hospital Construction Program, it has been estimated that the Nation needs at least 50,000 new tuberculo-

**school
health
services**

*a half century
of progress* →

sis beds. Others maintain that the ratio should be 1 bed per 1,000 population. Despite the need, only 2,000 new beds were added under the Hill-Burton program last year, he stated.

Last year too, approximately 2,700 tuberculosis beds went unused because of a nurse shortage. The shortage of physicians is equally pressing. We must turn to or develop other personnel, if we are unable to expand the output of our physicians and nurse training sources, said Dr. Anderson. Trained aides may substitute for professional nurses, but there is no substitute for a well-trained chest physician, he said.

Dr. Anderson stressed the importance of continuing to stimulate interest in tuberculosis on the part of younger medical men and of training more physicians in tuberculosis control. In one Federal Security Agency region, not a single State now has a State controller, although only a few years ago every State in that region had a full-time tuberculosis control officer.

Dr. Anderson warned against the relaxation of effort during recent years in case-finding activities. Two million less X-rays were taken last year than the year before. At the rate of one previously unknown active case per 1,000 people X-rayed, 2,000 contagious cases were not found. Thus, he said, the tuberculosis search must be intensified in population groups from which the disease is most difficult to dislodge—as among the Indians, who have a tuberculosis death rate 5 times as high as the population at large; among mental hospital patients whose death rate is 18 times higher; and among the Negro group in which tuberculosis is responsible for every fifteenth death.

Hospitalization and treatment must be complete, which means that the final stage of rehabilitation must not be overlooked, he summed up. The variation in range of rehabilitation services offered to patients is wide, he said. Rehabilitation is more a matter of philosophy of the

sanatorium staff than an additional, expensive service, he said.

Vaccination with BCG may offer some protection to persons who are exposed to tuberculosis, but "thus far we possess neither a widely specific cure nor effective immunization," concluded Dr. Anderson. "We do know, however, the methods that in the past have brought us partial success," he said, "and so we know full well what we must continue to do in the years to come."

The Older Are Hit Harder By Pulmonary Tuberculosis

Could the exposure of fewer children to tuberculosis infection account for the phenomenal decline in infectious cases among children under 10, asked Arthur B. Robins, M.D., Dr.P.H., director, bureau of tuberculosis, New York City Health Department, in his discussion of the age relationship of tuberculosis cases.

Dr. Robins noted a significant trend in tuberculosis epidemiology between 1932 and 1950: The proportion of new pulmonary tuberculosis cases occurring in persons over 45 had doubled; more than 65 percent of New York City residents who died from the disease were over 45; men accounted for 85 percent of the deaths; mortality from all forms of tuberculosis in children under 10 reached an all-time low.

The general decrease in infection, evidenced in fewer communicable cases, their more effective isolation, and the increased resistance of exposed individuals resulting from improved living standards, was undoubtedly a major factor in the decline of infectious cases among children, Dr. Robins said.

Children Under 10

To test the hypothesis that fewer children under 10 were exposed to tuberculosis, a study with far-reaching implications was undertaken in New York City households of male

index cases. A sample of 778 cases was selected at random from a total of 3,467 men over 25 with pulmonary tuberculosis reported for the first time in 1950. Both sample and total were divided into broad age groups: those 25 to 45, and those over 45. The data were analyzed by age and race distributions; by distribution of index cases and associates according to stage of disease; by relationship of associates to index cases; by distribution of index cases and associates according to household size; and by age distribution of household associates according to sex but exclusive of marital partners. Dr. Robins discussed the findings:

Pulmonary tuberculosis in older men is more advanced at the time of discovery—56 percent of males over 45, compared with 40 percent of men 25 to 45, had far advanced disease at time of the report. The percentages were almost reversed for minimal and moderately advanced stages of tuberculosis.

Diagnoses of Tuberculosis Are Major Concern

The dependability of bacteriological diagnoses of tuberculosis is a major concern of every laboratory director, Mildred B. Jefferies, M.S., chief bacteriologist, and Albert V. Hardy, M.D., director, bureau of laboratories of the Florida State Board of Health, stated.

Specimens for evaluation may deteriorate significantly during distribution, they said. Variations in findings when widely experienced bacteriologists examine the same specimen for tuberculosis is admitted. Controls may be used in checking techniques, as in staining, but not in measuring the sensitivity of the tests, they said.

Discussing their experience with 71,852 specimens examined by cultures and smear methods over 4 years, they concluded that more effective laboratory procedures were becoming evident.

Government, Industry, Labor In Industrial Hygiene

Government, industry, and labor all have responsibilities in developing sound programs of industrial hygiene, according to the papers presented to the industrial hygiene section of APHA. A representative of an official industrial hygiene agency outlined what he believes is government's function and indicated what is expected from industry and labor. Representatives of labor and industry named the services they need from the official agencies. They agreed that a high degree of agreement and cooperation among the three is essential.

Government's Function Is Study and Development

Government's primary function in the field of industrial hygiene is research and development, with direct services being provided by State agencies only when industry cannot assume the responsibility, maintained Henry N. Doyle, chief of the State aid branch, Division of Occupational Health, Public Health Service.

Outlining government's activities in meeting its responsibility "to show the way," he noted that the Public Health Service's Division of Occupational Health carries out a broad program, ranging from studies of health hazards resulting from occupational exposures to various toxic materials to projects affecting the entire well-being of the worker. It conducts field investigations and demonstrations; makes laboratory tests and studies; gives technical and administrative aid to the State and local agencies; provides infor-

mational services; and maintains cooperative relationships with other agencies and activities concerned with occupational health.

State and local industrial hygiene agencies, which are found in 43 States, 2 Territories, and 9 cities and counties, serve industry and labor and demonstrate techniques to help them solve their own health problems. Only in a few instances, he pointed out, do these units have law enforcement powers; generally, they have found educational methods to be much more effective.

Cooperation Expected

"From labor we expect a better understanding of the aims of occupational health," he said. "We expect labor to realize that industrial hygiene is preventive medicine and not a medical care program. . . . We seek labor's cooperation in carrying out occupational health studies. . . . We expect labor to be a part of the community, to demand minimum community health services where they do not exist."

He specified also that the union health and safety committees are of

invaluable assistance in solving industrial health problems and suggested that unions make better use of their opportunities for health education.

Mr. Doyle urged that management cooperate in industry-wide studies, receive the scientific reports made by the official agencies with open minds, and develop their own occupational health programs as rapidly as possible.

Above all, he said, both management and labor should bring industrial health problems to the attention of the local occupational health unit.

Commenting on accomplishments and current trends in the field, Mr. Doyle said: "Today, the average industrial plant is a safer place, accident-wise, than is the nonindustrial environment. The classical occupational diseases are no longer the 'black plague' of industry. We have seen industrial medicine progress from strictly an industrial trauma service to a real industrial health department."

He pointed out, however, that despite this progress, "only 10 to 15 percent of the working population have any occupational health facilities at their place of employment," a situation which he attributed to the remissness of industry and labor generally in accepting the responsibility for providing industrial hy-

a half century
of progress →

industrial
hygiene
surveys

glene services themselves, and to the lack of adequate funds and staff to enable the government agencies to even begin to do the job.

Better Public Agencies Desired by Industry

Competent, unbiased public industrial hygiene agencies sincerely trying to help industry provide better conditions for its workers will receive industry's admiration and support, Louis E. Newman, manager of the health and safety services department, General Electric Company, New York City, declared.

In stating the need for public agencies of industrial hygiene, Mr. Newman said that management is often unaware of job environments that adversely affect the health, productivity, or morale of its workers. He named as examples of mass occurrence of occupational diseases the cases of radium poisoning in the watch industry during World War I, beryllium poisoning in the fluorescent lamp industry following World War II, and silicosis in the mining and foundry industries.

Public industrial hygiene agencies can also serve as arbitrators through unbiased fact-finding and advice when management and employees differ about a hazard, he said.

Advice and Counsel

Industry, Mr. Newman said, needs advice and counsel from a competent public hygiene staff, but responsibility for correcting hazards rests with the operating management.

He stressed the need for recommendations that are sensible, practical, and economical. Industry must make a profit to survive and unnecessarily expensive control measures may work a hardship on a business.

Other important service characteristics listed for public agencies were dispatch and brevity in giving reports, agreement on uniform standards, accurate evaluation of the

problem, use of language that is understandable to the layman and is persuasive, and allaying of needless fears among employees during an investigation.

The minimum unit set-up should have proper balance in the fields of medicine, engineering, and chemistry, he said. Later, other more specialized fields, such as health-physics, biostatistics, and nutrition, can be added.

To get needed jobs done and to prevent omission of large areas, Mr. Newman suggested that the areas of Federal and State responsibility be clearly defined.

Study, Revision of Laws Suggested by Labor

Study and revision of present statutes so as to provide a clearly defined and complete industrial health service without overlapping of Federal, State, and local jurisdictions was urged by A. J. Hayes, president of the International Association of Machinists.

He reported that a paper is now being prepared by the Public Health Service listing various elements of an occupational health program. This, Mr. Hayes continued, should be of substantial assistance not only to legislators, but to management and labor alike.

Man-days lost because of illness are 35 times as many as lost from strikes and 10 times as many as from industrial accidents, he said, and this is not only unprofitable, but inhumane. "We cannot be complacent about ill health," he asserted.

A National Problem

The problems of industrial health can be dealt with more constructively if they are recognized as part of the national health picture, Mr. Hayes stated. The worker's health cannot be separated from a larger consideration of the health of those around him—his wife and children, his neighbors, the community, and

the Nation. A recent study by the Division of Occupational Health of the Public Health Service showed the number of absences due to nonoccupational illness or injury to be 116.8 per 1,000 for men and 256.4 for women, he reported.

Health is not only an individual but a national concern, the speaker emphasized; health is part of the national defense. Increased production will be the Nation's salvation; productivity lost because of sickness is a serious threat to America's defense and security, he maintained.

Inadequacy or lack of appropriations for health agencies, overlapping of jurisdictions, the shortage of medical personnel and facilities, and the cost of medical care and of health insurance all contribute to the "appalling" total—4,569,000 in February 1949—of persons who are absent from work on an average weekday because of illness or a disabling condition, Mr. Hayes said, and also help to explain why many industrial plants have not installed medical units.

In closing, the speaker agreed that the responsibility for overcoming these problems is not the sole responsibility of official health agencies, but belongs to every segment of society; that to accomplish the goal of better health services, industry must give full support and encouragement to every Federal and State agency which is promoting better health.

Connecticut Coordinates Worker Health Services

An occupational health program is concerned with all factors which influence the health of industrial workers, declared Stanley H. Osborn, M.D., and J. Howard Johnston, M.D., in their report on the program of the Connecticut State Department of Health. Dr. Osborn is commissioner of health and Dr. Johnston is director of the department's bureau of industrial hygiene.

In 1928, they stated, the bureau of industrial hygiene was established in the State health department to centralize industrial health work. This bureau is concerned directly with improving the environmental conditions in industry and with assisting in establishing well-organized industrial medical services. It also serves, they explained, as a coordinating unit through which services provided by other units of the State health department may be brought to the industrial worker.

Emphasizing that the bureau's staff of physicians, nurses, chemists, and engineers work as a team, Drs. Osborn and Johnston named the primary functions of each: Physicians appraise the worker's health in terms of exposure to toxic substances and to abnormal working conditions, interpret medically the interrelation of the industrial and nonindustrial environments upon the worker's health, and help industry in establishing nonoccupational health services; chemists study and analyze the environment of the worker to determine the nature and concentration of toxic atmospheric contaminants; engineers study methods of controlling these contaminants; and nurses contribute to the discovery of occupational hazards through their contact with in-plant nursing services.

Studies of Hazards

Investigations of occupational hazards mentioned in the report included determination of atmospheric concentrations of such materials as lead dust, chlorinated hydrocarbons, and toluol and the effect of exposure to the materials. In all studies of this type, Drs. Osborn and Johnston said, efforts are made to correlate results obtained from examination of body fluids with symptoms found among exposed workers. They noted also that the hazard involved in the use of recently developed insecticides, such as parathion, is being studied by the same methods.

Problems of radiation exposure, resulting from the new industrial

uses of radiol isotopes, X-rays, and natural radioactive materials, are receiving increased attention, they pointed out, as are the effects of noise and heat in industry.

The bureau's services are available at all times upon request from labor or management, medical director or plant nurse. In addition, they said, routine industrial hygiene surveys are conducted periodically, the interval between surveys depending upon the hazards associated with the manufacturing processes. New plants or changes in techniques and processes of old plants receive immediate investigation.

The bureau's value can be measured by the frequent calls for its services and the almost universal cooperation which it receives from industry and labor, Drs. Osborn and Johnston maintained.

Rusk Committee Studies Health Requirements

The reluctance of industry to employ more women, older workers, and the handicapped and the widespread lack of in-plant health services are two major barriers to the complete utilization of the Nation's manpower, asserted Seward E. Miller, M.D., chief of the Public Health Service's Division of Occupational

Health. These barriers are based principally on prejudiced and erroneous impressions, he said, and an educational program to dispel them has been inaugurated by the Health Resources Advisory (Rusk) Committee of the Office of Defense Mobilization.

One pamphlet prepared by the committee, entitled "The Worker and His Health," affirms that sickness absenteeism in industry, causing a loss each year of 400 to 500 million man-days, can be reduced by one-third to one-half with the establishment of in-plant health services, Dr. Miller reported. Three other pamphlets urge the utilization of women, older workers, and the handicapped in industry by showing that job performance records for these groups compare favorably with those of other workers. Dr. Miller emphasized that proper placement of these persons, considering all factors of special health problems, physical ability, and performance capability, enables them to perform many jobs successfully.

In-Plant Health Services

The committee has given considerable attention to methods of extending in-plant health service, particularly among smaller industries, Dr. Miller noted. Following a meeting with prominent leaders in the field of industrial medicine from universities, private industry, and vol-

control
of
malaria

untary and official organizations, which reaffirmed the committee's convictions that a great need exists for comprehensive in-plant health services, the committee designated a task force to investigate methods by which Government contractors could be induced to furnish at least minimal protective health services. Its efforts resulted in revisions to the Safety and Health Standards set up by the Department of Labor for the guidance of Government contractors. Standards dealing with

occupational health requirements were entirely rewritten under three headings: medical services, environmental conditions and personal services, and special sanitation services.

Other Activities

Since its establishment in August 1950, other accomplishments of the committee have been the creation of the Interagency Health Resources Council to coordinate the activities of medical-health agencies; the establishment of a single national

blood program coordinating the efforts of the Red Cross, the Armed Forces, and the Federal Civil Defense Administration; a study of civil defense health problems; and a review of military health personnel needs, resulting, to date, in estimated savings to the Armed Forces of 40 to 50 million dollars and the conservation of the services of 3,000 physicians for the civilian public. "All these activities," Dr. Miller stated, "either directly or indirectly, affect the industrial hygienist."

Methods of Administration In Medical Care Plans

Administrative methods designed to improve the quality of medical care were described in papers presented to the medical care section. These methods included: provision of medical care inside as well as outside the hospital, embracing both specialist and rehabilitation services; control of prescribing practices and of payments made to physicians under fee-for-service plans; and competent supervision of health insurance plans.

Regional Organizations Improve Health Services

Regional organization to improve health services for residents in the area of influence of medical teaching centers has been stimulated by the need for coordinating diverse health services and resources. This was one of the major points in a progress report on a survey of regional plans now being made by Leonard S. Rosenfeld, M.D., and Ruth Wadman, A.B., of the Division of Public

Health Methods, Public Health Service, and Nathan Kramer, A.B., Subcommittee on Medical Care, Committee on Administrative Practice, APHA.

Such regional organizations are designed to improve the quality and increase the availability and efficiency of all medical and related services within a community.

Their tentative findings are based on a survey of five such programs (those of the University of Colorado, Emory University, Medical College of Virginia, University of Buffalo, and the University of Kansas), and on a review of the published material on five plans still to be visited (Bingham Associates, Rochester Regional Hospital Council, New York University, University of Michigan, and Tulane University).

All plans, except Bingham Associates, which began in 1931, were launched in the 3- or 4-year period immediately following World War II, according to Dr. Rosenfeld and his co-workers. In eight plans the medical school has primary administrative responsibility.

In the other two, medical schools participate but the administrative responsibility is carried by another agency. Bingham Associates is a

philanthropic agency governed by a board of trustees; the Rochester program is governed by a board of directors composed of hospital and public representatives.

Community Services

The various services include graduate and postgraduate medical education and regular visits by consultants to hospitals, they continued. Several programs include educational and advisory services for hospital administrators and ancillary personnel.

Two of the plans have developed services for individual patients in addition to clinical consultation given as part of medical education.

Auxiliary services represent regional pooling of responsibilities ordinarily carried on by hospitals individually, such as central purchasing, blood bank, accounting and record systems, ambulance services, surveys and studies, Dr. Rosenfeld said.

All plans are designed to serve the practicing physician in the area. Some approach the physician directly, others through the hospital staff, some through both. In three plans all physicians in the areas are eligible to participate; in seven, hospital affiliation is a factor.

Financial Support

During their initial periods of operation, nine plans received support from philanthropic agencies. Tu-

lane received support from the Public Health Service. Buffalo and Kansas are also receiving support from their State governments. In all cases local financial support has been limited. The plans are now requesting financial participation by affiliated hospitals, voluntary agencies, and physicians. In Rochester, Blue Cross is contributing. From information accumulated thus far, it appears that the costs of maintaining regional services are relatively small when compared with the total costs of medical and hospital care in an area.

There is need for continuing experimentation, observation and evaluation, the investigators concluded. Because of differences in area, population distribution and density, in health needs and resources, in local traditions and attitudes, no single pattern of regional organization is suitable to all parts of the country, they said.

12 Years of Experience Modify Prepay Concepts

In discussing the early experience of the Associated Medical Services of Ontario, a Canadian prepayment medical care program, J. A. Hannah, M.D., its managing director, said that the years from 1937 to 1949 represented an organization period "during which many of our idealistic concepts were severely modified through experience."

"We believe attempts to provide such a service on a wholesale basis with insufficient experience has been, and will continue to be, the cause of failures and dissatisfaction on the part of both the public and the profession," he stressed, in reviewing experience of the plan approved by the Ontario Medical Association.

Accordingly, the Associated Medical Services was organized and maintained as a research project. Dr. Hannah's discussion was confined to a brief interpretation of special cost studies and to a statement

of the program's income and expenditures for the 12-year period.

Dr. Hannah reported that cost data are accumulated on a "number of months service rendered" basis for each year, which, he said, eliminates the making of adjustments for additions and subtractions from month to month.

Early Surplus Unlikely

He warned that in starting any medical prepayment plan, "too great optimism over a favorable surplus during the first 2-3 years is unwarranted," adding, "on the basis of our experience, we are beginning to feel that we may expect a crisis approximately every 5 years."

Dr. Hannah did not list the extent of medical coverage, but he remarked that in 1937 the Associated Medical Services was enthusiastic about "complete medical service," a concept which later was modified to check any trend toward insolvency. The first basic lesson learned, Dr. Hannah said, was that whenever the fund's solvency was threatened, services should be reduced but subscription rates should not be increased. Increasing rates retains subscribers who intend to make excessive use of their privileges but eliminates those who have not needed the service, he explained.

The Associated Medical Services withdrew well-baby visits and special nursing care, at an early stage,

because they were uncontrollable under a prepayment plan and strained harmonious professional relationships. Also, he added, it is not possible to retain solvency on a fee-for-service basis if home and office calls are included. The cost of administration is equal to or greater than the cost of actual service, it was discovered, and by paying a physician directly, patients get the same services at less cost. It was advisable to pay the larger bills which threatened family solvency, he said.

Obstetrical Load Heavy

According to Dr. Hannah, the plan paid out more than twice its expected share of obstetrical services because it appealed to subscribers in the child-bearing period. He mentioned an A. M. S. plan in preparation which will enable budgeting against cost of childbirth and prevent unfair use of the service at the expense of other subscribers.

Dr. Hannah considered coverage for people in later life well within the application of the insurance principle provided they have subscribed for "some considerable time prior to attaining that age."

One benefit from careful scrutiny of cost data was the observed increase in average costs. Dr. Hannah said these figures indicate the cost for each and every month's

appraisal of health services

service available, whether or not the subscriber sees his physician or enters a hospital. For example, among outstanding cost rises: X-rays doubled, rising from 5 cents in 1941 to 10 cents in 1949; anesthesia rose from 4 cents per month's service rendered in 1940 to 7 cents in 1949 and then increased more sharply; consultations stayed at 3 cents per month's service until the end of 1943, rising to 8 cents in 1947, and dropping to 7 cents in 1949.

Doctors, Miners Write "Finest Chapter"

The arduous, costly task of restoring men who have suffered crushed limbs and backs in the coal mines is "one of the finest chapters in the history of medicine," said Warren F. Draper, M.D., executive medical officer of the United Mine Workers of America Welfare and Retirement Fund in Washington, D. C.

In describing the UMWA medical care program, in operation 32½ months as of July 1, 1952, he stated that thousands of crippled miners have been restored to usefulness and reemployment, and that physicians in their devoted and selfless treatment of these men are bringing new knowledge of inestimable value to medical science.

UMWA Hospital Projects

The UMWA fund has been responsible for creating a memorial hospital association in Kentucky, Virginia, and West Virginia to construct, equip, and operate new hospitals in mining areas desperately needing hospital and medical care, Dr. Draper said. These three non-profit associations, organized under respective State laws, have built new hospitals to care for fund beneficiaries at Harlan, Pikeville, Hazard, Middlesboro, Whitesburg, and Wheelwright in Kentucky; at Wise in Virginia; and at Beckley, Logan, and Williamson in West Virginia.

Money for the memorial projects is provided by the UMWA Welfare and Retirement Fund through loans. The hospitals are open to members of the communities to the extent that their facilities are not needed by fund beneficiaries.

The fund neither owns nor operates hospitals but uses existing facilities according to convenience of location and willingness and ability to provide satisfactory service on an acceptable cost basis, Dr. Draper pointed out. Some 2,100 hospitals have cared for UMWA patients. Some 8,000 physicians have received payment for services. Of the combined cost of hospital and physician services, about two-thirds was for hospitals, and one-third for physicians.

Cost of Medical Care

"Completed data on hospital and medical costs in a program the size of our own should be of extraordinary value in charting the course of the future," he said in explanation of not publicizing itemized expenditures until costs have been stabilized to afford a reasonable basis for comparison with other plans.

Approximately 1½ million miners and their family dependents are potential beneficiaries of the program. The UMWA executive medical officer said that during the year ending June 30, 1952, 2,154,822 days of hospital and medical care were provided to 215,372 beneficiaries at a cost of \$49,996,517.88. Three percent of the expenditures for all medical care benefits represented the cost of administration of the medical and hospital service, including 10 area offices which cover the coal mining regions.

Services Provided

Services included in the program are: hospital care for such time as necessary, medical care in the hospitals, specialists' services outside the hospital as necessary, and rehabilitation services under the management of physicians at special centers.

Also included are drugs administered to hospital in-patients; certain expensive drugs requiring long, continuing use outside the hospital; physical examinations in connection with applications for prescribed cash benefits; and home and office care for severely handicapped patients following discharge from special rehabilitation centers.

The program does not include: dentistry, tonsil and adenoid removal, long-term treatment for mental illness, services for which the employer or some other party is legally responsible such as medical service in compensation cases, and available services which the patient may be entitled to receive from a Government agency, such as treatment for tuberculosis or mental disease in a State or county hospital, or from a private organization in the instance of tuberculosis, infantile paralysis, or cancer.

Baltimore City Reviews Prescription Practices

Increased prescribing of official drugs instead of proprietary preparations may be one way to lower the cost of public medical care programs, according to the findings from a study of prescribing practices in the Baltimore City medical care program.

The study was made and reported by Frank F. Furstenberg, M.D., director of the medical care clinic, Sinai Hospital, Baltimore, Md., Harry Goldberg, chief pharmacist at the hospital, Matthew Taback, M.A., director of the bureau of biostatistics, Baltimore City Health Department, and J. Wilfrid Davis, M.D., director of the medical care section of the department.

Drug Costs

Examination of 1,034 prescriptions, a 1-percent random sample of those written under the program between July 1950 and July 1951, revealed that over 55 percent were for proprietary drugs, the investiga-

tors stated. They estimated that an average of \$16.32 per 100 proprietary prescriptions could have been saved if official preparations having identical chemical, physical, and therapeutic properties had been used instead, representing a 6-percent reduction in drug costs for that year.

From the beginning of the Baltimore City program, drug costs have constituted a significant portion of the total budget, amounting to 30 percent during the study year, Dr. Furstenberg and his associates explained. Since the program specifies few prescribing restrictions, examination of the drug problem was considered necessary for proper administration.

Quality of Service

The study also provided data which, they said, permits certain inferences concerning the quality of medical care being provided. Among these data were the following:

Thirty-seven percent of the prescriptions were for "therapeutically nonacceptable" preparations, using as the criterion of acceptability the inclusion of the preparations in the United States Pharmacopeia, the National Formulary, or the American Medical Association's New and Nonofficial Remedies.

Forty-four percent of the prescriptions from private practice were for nonacceptable preparations, but only slightly more than 16 percent of those written in the hospital were so classified.

Refills

Fourteen of the prescriptions provided therapy for nearly a year; 31 percent of the prescriptions for sedatives, other than phenobarbital, allowed two or more refills.

Predominant types of prescriptions were for cardiac, respiratory, and gastrointestinal preparations, the preparations being classified according to probable physiological action. Analgesics ranked fourth and sedatives fifth.

Over 50 percent of the prescriptions for insulin and allergy preparations were written in the hospital medical care clinics or out-patient departments, whereas tonic and placebo prescribing was rare in these places.

Limitations Recommended

Dr. Furstenberg and his colleagues recommended, in view of these findings, that consideration be given to limiting the duration of therapy allowed on a single prescription and the number of refills allowed. Unlimited prescribing may be an important factor both in high drug costs and in questionable medical practices, they indicated.

They suggested that prescribing practices might be improved by including, in a public medical care program, education in prescription writing for the participating physicians. The use of a formulary, they said, would effect immediate economies.

Statistical Procedure Charts Fee Pattern

The administrative control of payments made to physicians on a fee-for-service basis can be accomplished by use of statistical methods, Charles

A. Metzner, Ph.D., research associate, S. J. Axelrod, M.D., associate professor, and J. H. Sloss, M.A., research assistant, all of the bureau of public health economics, University of Michigan School of Public Health, Ann Arbor, found in a study of a comprehensive prepayment plan.

Payment Methods

Expansion of medical care insurance plans will likely be based on services embodying the fee-for-service method of payment, and the problem of control of payments to physicians is increasing in importance, the Michigan investigators stated. Financial stability of any medical care program demands that receipts exceed the expenditures, they said, and in a fee-for-service plan, unlike the automatically controlled capitation and salaried systems, no inherent limit is set on the physician's income.

Analysis of available data showed abuse of services by subscribers to be minor, whether measured in terms of excessive demands for service, "shopping around" for physicians, unreasonable requests for medical care outside regular hours, or overutilization of services. The investigators therefore concentrated their study on the control of abuse by physicians in "rendering fees." Heretofore, no objective method of

Financial grants-in-aid from Federal to State and thence to local governments—plus loan of personnel and technical assistance—proved a significant catalyst in the growth of services and facilities for the safeguarding and promoting of the public's health.

ing the first year of the plan was designed to reimburse hospitals according to their ability to provide a complete service and also to stimulate improvement in equipment and personnel, they said. Under this system some hospitals were making substantial profits, a few were breaking even, but many were incurring deficits.

When it became evident that there is no close relationship between the quality of service and the cost of providing it, this system was superseded by per diem payments based on estimated costs, the officials reported.

Under this system the in-patient hospital revenues fluctuated almost directly with seasonal variations in occupancy, thus creating some difficulty in financing fixed expenses during low occupancy periods, the officials stated. They also pointed out that some hospitals found inclusive per diem rates an incentive to overcrowd, because a drop in occupancy meant a corresponding decrease in revenue.

Plan Sound and Workable

Both the hospitals and plan officials are pleased with the present method, they state, terming it "a sound, workable, equitable method of remuneration of hospitals for coverage under a comprehensive hospital insurance program."

The Saskatchewan Hospital Service Plan, administered by the provincial Department of Public Health in consultation with representatives of the hospitals, makes essential hospital care available on a free choice basis. It covers about 94 percent of the population in the province, or about 780,000 persons. The program is financed through obligatory personal premiums, except for the indigent, and through supplementary provincial taxation. The benefits include minimal or public ward accommodation and virtually the entire range of available in-patient service.

Scientific, Group, and Community Approaches to Obesity

The problems relating to obesity, benefits to be secured through weight reduction by overweight individuals, and various approaches to weight control were considered in a panel discussion before the food and nutrition section. Five of the papers presented are summarized here. Another paper dealing with the approach to weight control was read to a combined session of the food and nutrition and health officers section.

Louisville's Experience Points Up Obstacles

The many followers of reducing fads and the increase in sales of over-the-counter obesity drugs and dietetic foods reveal an ignorance of the obesity problem as well as general interest in its control.

This observation was made in reporting the weight control project sponsored in 1951 by the Louisville, Ky., Nutrition Committee. Four of its members who presented the committee's findings are: John S. Llewellyn, M.D., Louisville Heart Association; Emily Bennett, B.S., executive director, Central Dairy Council; Mary M. Hurley, M.P.H., health educator, Louisville and Jefferson County Board of Health; and Mildred Neff, M.A., director, division of nutrition, Kentucky State Health Department. They reported:

The instructors of the committee's weight control classes and education program were faculty members of the University of Louisville School of Medicine, teachers and community professional workers in economics, nutrition, health and physical education, and directors of insurance companies.

A physician explained the undesirable effects of rapid weight loss, use of unapproved drugs, and the fads sometimes offered in the daily papers. Lectures were held on topics including reasons for overweight, diet, the advantages and disadvantages of exercise, and the fallacy of exercise as a substitute for decreased caloric intake, and the rewards for normal weight.

Results of Program

Encouraging was the average weight loss per person of those who attended classes during the first 3 weeks. Seventy-seven (96.2 percent) lost weight in significant amounts, two maintained initial weight, and one gained weight. For this group the weight loss ranged between $\frac{1}{2}$ and $12\frac{1}{4}$ pounds for an average of 5 pounds per person during the first 3 weeks of the classes.

At the end of 26 weeks, 19 of the original class were present. Of these, 79 percent had lost weight, 3 persons had gained, and 1 showed no change.

Attendance records were discouraging, however, in spite of excellent publicity through all media of information. This indicates inertia inherently present in the public for community service. More interest probably could be obtained by appealing to the obese person individually than collectively.

Less than 1 percent of the total attendance of the classes were men. It seems advisable to offer sex-segregated classes so that men will participate. Overweight is less harmful to women than to men so far as longevity is concerned, but women are more inclined to correct overweight than men.

Great interest was shown in the graphic displays prepared by the insurance companies which statistically depicted analyses of obesity.

The obese person must be properly motivated to reduce, the committee members emphasized. In future programs therefore, the psychotherapeutic approach is to be incorporated as an integral part of the classes in hope that results will be better.

Obesity Is a Factor In Arteriosclerosis

Deaths from arteriosclerosis occur earlier in the overweight than in the nonobese population. This one fact about arteriosclerosis stands out with clarity, Norman Jolliffe, M.D., director of the bureau of nutrition, New York City Department of Health, stated.

The only advice that can now be offered with confidence on prevention of arteriosclerosis and related diseases is "never become overweight, and if overweight, reduce and stay reduced," Dr. Jolliffe said. By this means alone, he believes Americans could increase normal life expectancy by 1, 2, or perhaps even 4 years.

Dr. Jolliffe termed arteriosclerosis and the degenerative diseases as the health problem to be reckoned with in this day of an older population, when 90 percent of the people will live to and beyond the age of 45 and the life expectancy is 67.6.

People are eating as much now as they did in 1900, he said. The daily calorie consumption per person is still 3,100. As an older, less hard-working population, they should be eating less—2,870 calories per day. The need for calories decreases about 7.5 percent for each 10 years after age 25, and with easier transportation and labor-saving devices, less energy is being expended, he explained.

It has been estimated that 25 to 30 percent of the population is over the desirable weight, Dr. Jolliffe said.

Basic Principles For Reducing

He outlined three basic principles that must be applied if America's

number one health problem, obesity, is to be solved:

First, obesity is invariably caused by a greater intake of calories in food than expenditure of calories as energy. This statement leaves no "out" for the overeater who sees himself as an exception to the rule.

Second, loss of excess fat is directly proportionate to the calorie deficit, which can be obtained either by increasing the calorie expenditure or by decreasing the calorie intake. To lose 2 pounds the obese person must eat 1,000 calories less a day for a week. The equivalent in calorie expenditure, or exercise, would be 5 extra hours of walking.

Third, the reducing diet should form the basis of dietary reeducation so that proper eating habits will continue after the desired loss of weight. Skipping meals or following trick or rigid diets the person does not really understand does not establish good dietary habits. People should learn food values and how to count calories.

Five Research Methods Determine Obesity

In a discussion on criteria of overweight, John H. Browne, M.D., of the New York State Department of Health's bureau of nutrition, described five research methods of determining obesity.

With anthropometric instruments, take precise measurements of the body between designated bony landmarks and determine circumference and diameter of the trunk and extremities.

X-ray the leg or other parts of the body, cut the film along the lines of shadow of bone, muscle, and subcutaneous tissue, and skin, and weigh the pieces of film; or measure the area of the various shadows.

Determine the creatinine coefficient (said to be uncertain method).

Estimate total body fat from body water.

Determine the specific gravity of the body by weighing in air and under water; the percentage of fat can then be found by referring to tables developed by Rathbun and Pace.

Practical Methods

In everyday practice, however, simply looking at the patient is usually sufficient to determine overweight, Dr. Browne stated. The scientific techniques described are expected to add to our knowledge of precise determination of overweight and to aid in studying groups of people with regard to calorie nutritional status.

In total weight measurement, the amount of muscle and bone must be considered because of variation among individuals, Dr. Browne pointed out. By the scales, a professional football player may seem to be 30 pounds overweight, whereas a muscularly underdeveloped individual may be within the average for his height and still have an excess of fat, he explained.

Reduction in Weight May Lengthen Life

Although weight reduction is not a panacea for all of the difficulties of the overweight person, it can bring him substantial physical, psychological, social, and economic benefits, make him look and feel better, and probably lengthen his life, commented Louis I. Dublin, Ph.D., second vice president and statistician, Metropolitan Life Insurance Co.

Nevertheless, there is a "surprising dearth of information on the benefits of reducing" due to difficulty in assembling the facts and the needed long-term follow-up, he stated.

A study of 25,000 men and 25,000 women who, because of obesity, were charged an extra premium by his company revealed nothing start-

ingly new, he said. Mortality was 50 percent higher among the obese than among "standard insurance risks." However, in a special study of those among the overweight who had reduced, the death rate was found to be one-third lower for women and one-fifth lower for men than the rate for the overweight group, he reported.

Diseases Among the Obese

Diseases of the cardiovascular-renal system, diabetes, and disorders of the liver and biliary tract cause excess mortality in the obese, Dr. Dublin stated. Various studies have also shown that gallstones, gout, vascular complications, hypertension, asthma, and bronchitis have a higher incidence among the overweight, he noted. The stillbirth rate among obese women is nearly double the rate among women of normal weight.

Dr. Dublin observed that overweight may seriously handicap individuals, regardless of age or sex, in their personal lives, in employment, and in social relations. A fat child ridiculed by other children is likely to seek satisfaction in sedentary recreation and in eating.

Weight Control Groups Studied by Conference

The group approach gives promise of achieving a program of weight control, but it is not the answer to all of the problems.

This was the conclusion reached by participants in a Conference on the Group Approach to Weight Control held in Washington in June 1952 as reported by Malcolm J. Ford, M.D. Dr. Ford is chief of the program development branch, Division of Chronic Disease and Tuberculosis of the Public Health Service.

The purpose of the conference, as stated by Dr. Ford, was to bring together people with experience in the

group approach to weight control and to find out the opinions they hold in common as well as the points of difference.

The conference thought that weight control groups should be: homogenous in terms of age, background, and degree of overweight of participants; heterogenous in terms of personality; small in size (10 or 12 ideal); screened to eliminate those not likely to benefit from the experience and those with severe psychological problems; assembled in short sessions not too frequently held (1 hour once a week, tapering off to once a month); supervised by medical personnel, but leader need not have any particular type of professional training.

Some believed that group members should weigh in at each session. Others felt that this was unimportant or even detrimental. Some thought that proper nutritional information alone was all that people needed; others stressed the psychological aspect of weight reduction.

Factors Leading to Obesity

Although not the primary subject of the conference, the factors that lead to obesity were discussed. The discussants agreed:

Some people have special difficulty in hewing to a dietary line, such as those with certain ethnic or cultural food patterns.

People with little money tend to buy the cheaper carbohydrates.

Mothers after delivery fail to lose excess weight gained during pregnancy.

Emotional problems alone may be responsible for overeating.

The conference, Dr. Ford said, recommended that other controlled studies be carried on to investigate the effectiveness of the group approach as compared to the individual approach to weight control. First results from experimentation with the method were inconclusive but interesting. Before the method is advocated unreservedly, more scientific observations are needed to clear up unanswered questions.

Community Can Attack Problem of Obesity

Obesity, a threat to health and life expectancy, is an important public health problem which the community can attack, suggested W. P. Shepard, M.D., third vice president of the Metropolitan Life Insurance Co., San Francisco.

Overweight afflicts approximately 15 million people in the United States, making them especially susceptible to heart disease, kidney disease, apoplexy, diabetes, and other degenerative diseases, he said, adding that people become interested in weight control as they become aware of the health hazard of overweight. The individual's responsibility for control of his own weight must be developed by a continuing health education program.

Leadership for the community weight control program can be assumed by the major local health agency, health council, or officials, Dr. Shepard pointed out. Professional people, aware of the importance of correct weight, are valuable collaborators, he said. In addition those already interested in "reducing," can be utilized in program planning.

Arouse Public Interest

Communities will differ in resources, leadership, and interested groups, said Dr. Shepard. To arouse public interest and to stimulate individual responsibility, agencies participating in the weight control program should include: health departments, heart associations, hospitals, schools, clubs, church groups, civic organizations, and professional societies of physicians, nurses, and home economists. Sponsored programs can be public panel discussions, club meetings, movies on health subjects, symposiums and institutes for organization members, group therapy, home visits by professional health workers, and pamphlets, posters, and exhibits widely distributed and regularly issued.

Cooperative Group Action by Parents of the Handicapped

How parents can help their handicapped children, what can be done to prevent other and unborn children from being handicapped, the various difficulties faced by the parents themselves—these and similar problems were discussed before diverse sections of the conference.

Group counseling was the keynote. It was felt that the more information received by the parents, the more counseling provided for understanding their own and their children's problems, the better equipped they would be to promote a happier and more constructive life for all concerned.

Group Discussion Enhances Child Health Interviews

To the traditional individual interview procedure of the child health conference has been added the group discussion method, reported Samuel M. Wishik, M.D., M.P.H., professor of maternal and child health, University of Pittsburgh Graduate School of Public Health. He told a joint session with the Conference for Health Council Work about administrative experimentation in 1950-51 with the new technique at the Lillian Wald Child Health Station, one of the 80 stations operated by the New York City Health Department.

Dr. Wishik believes that the individual approach and the group approach can be satisfactorily combined. "It is conceivable," he said, "that the group method might economize in use of professional staff time. If certain common questions

can be answered for groups of mothers effectively, it might not be necessary to go over the same material separately with each mother. Furthermore, if certain common problems are put across with mothers in general, it may make it possible for the professional staff to devote its time in the individual interviews to other phases of parent counseling."

Dr. Wishik admitted that in its early stages group discussion is an additional task for the professional staff, requiring more rather than less time.

He remarked that the group method of idea exchange should aid in effective counseling because mothers "support and bolster" each other in the group and are more receptive to changes in child-training when they receive "ideas from their peers rather than from a professional group." Mothers, he said, are more strengthened by group discussions with other mothers in changing their practices and in substantiating some of their convictions about existing practices.

Professional Attitudes

The group technique may develop a change in staff attitudes and methods if the staff member can acquire from group discussion the habit of "listening more and of getting a more accurate impression and more intimate feeling of the experiences and points of view as well as problems of the mothers," he commented. Dr. Wishik hoped that such an attitude would carry over into the individual interview relationships between the physician or nurse and the mothers. He indicated a possible application of the group method to the private office practice of pediatricians.

These factors were selected by Dr. Wishik for successful free group discussion:

1. Skill of the discussion leader and nature of the participation of the physician and nurse.
2. Smooth functioning of gathering of mothers: avoidance of undue waiting time and noninterruption of discussion by outside factors.
3. Appropriateness of the topics to the interest of the mothers.
4. Size of the group.
5. Personality of the participating mothers.

New York Experience

At Lillian Wald, he said, 25 minutes were set aside on Thursday mornings at 10 o'clock for 12-15 mothers to meet in a large room separate from the waiting room and the children's play area. The time chosen permitted parents to have their individual interviews in the preceding hour. Seats were arranged in an informal circle. While no children were included, they had free access to their mothers from the play area where they were kept under supervision.

Parents with similar backgrounds and common problems and unhampered by language difficulties were grouped in conference periods on separate Thursdays according to the age of their youngest child. A spread in the children's ages within each span was considered desirable so that the mother who had already met a situation, such as introducing the first solid foods, could relate her experiences.

Sample topics for mothers with children from 10 to 12 months included: thumb sucking, colds, going to sleep, fear of strangers, clinging to parents, shoes, walking, weaning, bowel training, and feeding. Similarly appropriate topics were chosen for the other age spans: birth to 6 weeks, 7 weeks to 3 months, 4 to 6 months, and 7 to 9 months.

When the regular station physician and nurse participate in discussions, they can interject helpful questions, Dr. Wishik commented.

"Physicians and nurses repeatedly evidenced surprise that mothers raised questions which they had not asked in individual conferences," he noted. "When the doctor recommends something different from what was taught several years ago, a mother can ask the reason for the change in recommendation," giving him an opportunity to interpret the reasons for changes in teaching.

Parents Attend Classes On Care of Premature

Although the "premature program" is still new, it has been extremely valuable in helping parents to give better care to premature babies, Gellestrina DiMaggio, M.N., and Marguerite B. Gelinis, B.S., M.S.S.W., told the maternal and child health, public education, and public health nursing sections of the American Public Health Association and the Conference for Health Council Work.

Miss DiMaggio is administrative supervisor of children's service, Grace-New Haven Community Hospital, and clinical instructor in the Yale School of Nursing; Mrs. Gelinis is a pediatric social worker at the Grace-New Haven Community Hospital.

The key part of the program, they said, is the monthly group meetings held at the hospital, when parents, grandparents, or others assisting in the care of the baby are encouraged to ask questions and to discuss their problems.

The meetings are informal, they continued. The children's ward resident presides and a nurse and social worker help in the discussion. The nurse tells about the nursing care of the baby in the premature nursery, answers questions about his care after he is discharged, and encourages the parents to come in at any time to care for and get acquainted with their baby. The speaker stressed the importance of the visiting nurse in giving the

mother a sense of security in bridging the gap between hospital and home.

Parents' Queries Answered

The social worker described her functions, among which is the encouraging of parents to bring before the group questions they have asked her. These most often concern the reason the baby was premature, what can be expected in his growth and development, the danger of overprotection, preparation of other children at home for the advent of the baby, effect of the parents' feelings upon their care of the baby, insecurity in caring for a small infant, and fear that he may be fragile or that they may expect too much of him.

Parents feel that they have adjusted to their baby more easily as a result of these group discussions, they said, and the staff has learned a great deal, including the fact that more than a simple explanation about prematurity is needed by parents, and that the parents work more effectively with the hospital after attending meetings.

Mentally Retarded Aided By Group Methods

When one New Jersey mother advertised a few years ago that she had a mentally retarded child and asked other mothers to phone her about discussing their common problem, she sparked a remarkable group method, E. Louise H. Porter, Ph.D., registrar at the Southbury Training School, Southbury, Conn., told the joint session with the Conference for Health Council Work.

The New Jersey parents met, sought professional advice, and set off a chain of national, State, and local organizations to help overcome parental and social misunderstanding of mentally defective children, Dr. Porter noted.

"I doubt if a better group method exists," she said. "It is dynamic

because it derives from the long-suppressed feelings of parents who always believed, though silently and alone, that something should be done. To be sure, a few parents never had the belief, and some parents had lost it when they were convinced that their child should be institutionalized and forgotten. These organizations of parents have given their members faith in themselves and their children . . . This wholesome attitude engenders an improvement in the attitude of others."

The Children Improve

Effects of the new parental attitude on the children themselves are far-reaching, she continued. "Some children are enjoying the company of others of their own mental level for the first time in their lives. Others are going out into the world from which they were previously separated by shame. Still others are attending classes though they had formerly been excluded from school as noneducable. A few others are obtaining jobs because intolerance of slowness has given way in a few places. This is only the beginning."

The group method has spread to institutions too. "Previously parents traveled from many geographic areas to visit their children and returned quickly to their separate homes," Dr. Porter added. "Now they not only visit their children but remain to meet with other parents for group discussions."

Dr. Porter commented that through appreciation of an institution's problems parents have provided "the administration with a bulwark of backing when outside influences try to alter the school's carefully developed philosophy. Parents drawn into these groups have a new purpose in life, and those whose children have been living in the institution for years wish they had been wise enough to start discussions long ago. As if to compensate for the years they lost, many of them join the community groups and help bring understanding to other parents."

Group discussion is leading to action as parents realize their power as a group. Action is what the field of mental deficiency needs to obtain funds for special classes and recreational opportunities, to convince industry that the more capable mentally deficient are good employment risks, and to stimulate the professions of medicine, psychiatry, education, psychology, and social work to train their specialists for wise guidance of the mentally retarded child and his family, Dr. Porter stressed.

Own Problems Solved By Parent Groups

Intelligent group counseling by psychologists and medical social workers with parents of cerebral palsied children helps to eliminate many of the parents' misconceptions about cerebral palsy and aids them to a fuller understanding of their part in their children's development, said Harry V. Blee, Ph.D., consulting psychologist with the Bureau of Crippled Children, New Jersey State Department of Health.

Such a group counseling program was inaugurated in New Jersey, Dr. Blee reported, because parents did not feel they received adequate information about the complex nature of cerebral palsy from the professional physicians, nurses, and therapists treating their handicapped children.

He said many parents needed release from emotional tensions, as well as pertinent information about their children. They frequently expressed resentment, complaining either that they were unjustly burdened with an afflicted child or that professional personnel were not competently treating the child. To meet this dual need throughout the State, counseling groups were organized which were small enough to enable the counselor to know each child and his particular problems and to

provide parents with an opportunity for self-expression.

Subtlety in Counseling

Nondirective group counseling was emphasized, with the counselor attempting to remain in the background while parents discussed and offered their own solutions to problems that were presented. Even when it was necessary that the counselor give technical information, he tried to draw from the parents their own points of view.

Best results were achieved, continued Dr. Blee, when fathers and mothers were not both present at the same meeting, for while a mother might speak freely of tension between herself and her husband when only other mothers were present, she was unlikely to do so if he or other men were at the meeting. Therefore, five separate meetings were conducted for each group, with a sixth and summary meeting being participated in by both groups. More women than men attended the afternoon meetings, he said, and recommended that meetings for men be held at night.

Generally, Dr. Blee concluded, the parents discussed candidly their feelings of embarrassment, frustration, and guilt toward their children and contributed greatly to each other in comparisons of disciplinary and training methods.

That "Different" Feeling Mitigated by Groups

Four advantages of informal group discussions among parents of chronically ill children were outlined by Luigi Luzzatti, M.D., at a combined session of the maternal and child health, public health nursing, and public health education sections and the Conference for Health Council Work.

Dr. Luzzatti, chief, department of medicine, Children's Hospital of East

Bay, Oakland, Calif., said that the discussions held in the metabolic clinic for parents of diabetic children have provided the parents with accurate information about the disease; have helped them overcome the feeling that they or their children are "different" or "alone"; have helped to release parental anxieties; and have provided the professional staff with information about the parents and children.

Pointing out that the care of a child with chronic disease requires more than regulation of the disease, he maintained that there are limitations as to how much can be accomplished by the one-to-one contact between physician and parent in the doctor's office or clinic. Admitting this contact is useful, he expressed the belief that group discussions can significantly supplement it.

Information and Reassurance

Participating in the group discussions described by Dr. Luzzatti were the professional personnel who see the parents and children individually in the clinic and one or both of the parents of 13 of the 20 children attending the clinic.

Discussions centered generally around assigned topics such as physiopathology of carbohydrate metabolism and diabetes, management of the diabetic child, psychological adjustment to the disease, and economic problems of care. Many of the questions raised by parents stemmed from ignorance of a particular aspect of the diseases; others from a simple need for reassurance.

In retrospect, Dr. Luzzatti said, it is believed that the discussion would have been more valuable had more stress been placed on the individual problems and less on imparting information on a planned basis. "We came to feel," he stated, "that only out of an answer to their own individual problems would parents derive the ability to accept the condition and to reassure each other."

Studies of Spread Patterns Of Infectious Hepatitis

Observations on infectious hepatitis in a Baltimore housing project suggest the use of gamma globulin to stop an outbreak. Further observations in Philadelphia confirm data indicating the fecal-oral type of spread of the agent. In National Microbiological Institute investigations, heat of 60° C. fails to sterilize plasma infected with the agent of homologous serum hepatitis.

One of these studies was presented to the epidemiology section and the other two to the joint session of that section with the laboratory section.

Radial Pattern Revealed In Hepatitis Outbreak

The nearer a person lives to a home affected by infectious hepatitis, the greater is his risk of contracting the illness.

This was the opinion expressed by Abraham Lillienfeld, M.D., Irwin Bross, Ph.D., and Philip E. Sartwell, M.D., of the departments of epidemiology and biostatistics, Johns Hopkins University School of Hygiene and Public Health.

Focus of Infection

Basing their conclusions on an intensive 2-month study of an outbreak of infectious hepatitis in a Baltimore housing project in 1951, the authors stated that the disease seemed to spread from a focus near the center of the project in a radial pattern often seen in outbreaks of poliomyelitis or measles.

The Baltimore City Hospitals, located near the project of row

houses, alerted the city health department to the outbreak in July 1951. Approximately 30 cases were reported from April through September although reporting of jaundice was not required. The study was initiated to determine the number of cases and the distribution according to various characteristics of the industrial population.

Method of Attack

Interviews with residents and their physicians established that there had been 117 mild cases of infectious hepatitis among the 3,970 residents during the year prior to the study. Eight cases without jaundice were not included in the study. The general attack rate was 2.9 percent, the highest occurring in the 5-14 age group. Females had a higher attack rate than males.

Examination of school attendance records, income status, duration of residence in the city and in the project, and the history of parenteral injections did not implicate these factors in the outbreak. In fact, newcomers to the project had a lower attack rate than others, contrary to the observations made on military populations.

During the outbreak, gamma globulin was offered to some of the persons of the affected households. The total secondary attack rate for those not receiving gamma globulin was 8.8 percent, which is considerably lower than the secondary attack rate reported in other outbreaks. The attack rate among those who received the globulin was 1.4 percent.

The expected seasonal decrease was observed in the summer months with a decided increase occurring in the early autumn. Because of the pattern of distribution, the authors determined that the disease was transmitted by the fecal-oral route.

The observed pattern might be utilized as a basis for applying gamma globulin in civilian populations to stop an outbreak, the authors suggested. "In institutional outbreaks it is feasible to administer gamma globulin to all the inmates. Although this is impossible in civilian life, it would be feasible to administer gamma globulin to members of the households which are in close proximity to an already affected one since their risk appears to be greater than average."

Hepatitis Transmission Via Fecal-Oral Route

The failure of nurses in a Chicago orphanage to properly wash their hands after each change of infant diapers was a major source of infectious hepatitis in one of the classic institutional outbreaks.

Most of the essential epidemiological points gleaned from that outbreak were discussed by Joseph Stokes, Jr., M.D., professor of pediatrics of the School of Medicine of the University of Pennsylvania. In outlining the epidemic, which pointed to the fecal-oral route of transmission, he reported the following:

Peculiarly, the disease seemed to appear only in new student nurses shortly after they began their training and did not seem to appear in the children or other adults at the institution. The knowledge of the presence of the disease there since 1942, and the fact that new interns also had begun to contract the disease, began by 1948 to deter new interns and nurses from applying for admission.

Gamma Globulin Injected

After November 7, 1948, gamma globulin was injected as a palliative and diagnostic measure into all new student nurses upon admission. Just prior to that date, 42 of 144 incoming students had developed jaundice soon after admission. In the 36 nurses who received the gamma globulin injections no jaundice de-

veloped for the succeeding 10 months. One exception was noted—a nurse who received her globulin 2 days prior to onset, a fact which confirmed the continuing endemic nature of the disease.

Skin tests for the presence of virus in the stools of certain children were conducted and evaluated. An evaluation of orphanage personnel, a tracing of possible sources, and hepatic function tests on key children and adults were made.

The liver function tests pointed to the fourth and fifth floors as the locale of the diseased children—over 80 percent of the student nurses who developed jaundice during the period from January 1, 1946, to November 7, 1949, had done so within 3 weeks of entering or of leaving the fourth and fifth floors. None of the mothers contracted the disease even though they were exposed to contact with the student nurses and ate and drank the same food and water.

The gamma globulin injections were halted on September 1, 1949, at which time 20 new nurses were admitted, 9 of whom developed hepatitis.

By use of volunteers, the presence of active cases of hepatitis A or of intestinal carriers was demonstrated by testing stool preparations from two children who had symptoms and positive liver function tests.

Hand Washing Effective

Following careful instructions on hand-washing techniques, no jaundice has occurred even in the absence of gamma globulin since December 1949 to the present time.

The outbreak supports other data indicating hepatitis A has a fecal-oral type of spread and does not appear to spread by nasopharyngeal secretions. A respiratory route of transmission would have brought the disease to at least one of the mothers in the Chicago orphanage, and the simple improvement in the cleanliness of nurses would not have stopped the disease if it had a respiratory route of spread from child to nurse.

The incubation period of epidemics of this disease is from 20 to 35 days but may be increased by attenuation of, or decrease in the number of, viral bodies in the infective material.

Immunity Attained

Individuals can be chronically active cases and carry the virus in their stools. Gamma globulin, administered at least 7 days prior to expected onset, is effective, at least as a temporary protective agent, in doses as small as .01 ml. per pound body weight. There is the suggestion that passive immunity can be changed to passive-active immunity if the individual continues at risk during waning passive immunity.

It appears best to have experience with the virus at an early age since jaundice is rare in hepatitis cases in the youngest age groups. Recently developed skin tests suggest that the hepatitis A virus, like measles or mumps viruses, may be of uniform antigenic properties which produce permanent immunity.

Virus of Serum Hepatitis Survives Heat

Plasma infected with the agent of homologous serum hepatitis retains its ability to produce jaundice even after being heated at 60° C. for 4 hours, reported five researchers in the laboratory of biologics control, National Microbiological Institute, National Institutes of Health, Public Health Service.

The study from which this conclusion was made was described by Roderick Murray, M.D., William C. L. Diefenbach, M.D., Frank Ratner, M.D., and Nicholas C. Leone, M.D. It is one of several being conducted to determine the effectiveness of existing and proposed methods of sterilizing blood and blood products.

Volunteers Inoculated

According to the investigators' statements, the study involved the

inoculation of three groups of volunteers with samples from a pool of infected plasma: one group of 10 men was inoculated with 1.0 ml. of plasma which had been heated for 2 hours; a second group of the same number, with 1.0 ml. of plasma which had been treated for 4 hours; and a third group of 5 men, with 1.0 ml. of plasma which had remained at room temperature. The heating had been accomplished by suspending 10-ml. bottles containing 7 ml. of infected material in a water bath, with each bottle completely immersed. The water was constantly agitated and the temperature maintained at about 60° C.

Dr. Murray and his associates stated that three cases of frank jaundice and one showing clinical signs and symptoms of hepatitis but with no visible jaundice occurred in the group inoculated with plasma heated for 2 hours; three cases of frank jaundice and two cases showing abnormal laboratory findings occurred in the group which had received the plasma heated for 4 hours; and one case of frank hepatitis occurred in the group which had received the control material.

Health Hazard Guarded

Subjects participating in this and other studies, Dr. Murray and his colleagues explained, are inmates of Federal penitentiaries, over 21 years of age but below middle age, who volunteer for the experiments. Each volunteer is carefully screened by a review of his past medical history, a complete physical examination, and a battery of liver function tests. After inoculation with the test material, the subjects are examined weekly. They are questioned as to their health, observed closely for possible icterus, and examined carefully for the development of signs of hepatitis. In addition, the set of liver function tests is repeated. On development of sustained symptoms or abnormalities, the subject is hospitalized for observation and treatment.

Studies of Spread Patterns Of Infectious Hepatitis

Observations on infectious hepatitis in a Baltimore housing project suggest the use of gamma globulin to stop an outbreak. Further observations in Philadelphia confirm data indicating the fecal-oral type of spread of the agent. In National Microbiological Institute investigations, heat of 60° C. fails to sterilize plasma infected with the agent of homologous serum hepatitis.

One of these studies was presented to the epidemiology section and the other two to the joint session of that section with the laboratory section.

Radial Pattern Revealed In Hepatitis Outbreak

The nearer a person lives to a home affected by infectious hepatitis, the greater is his risk of contracting the illness.

This was the opinion expressed by Abraham Lillienfeld, M.D., Irwin Bross, Ph.D., and Philip E. Sartwell, M.D., of the departments of epidemiology and biostatistics, Johns Hopkins University School of Hygiene and Public Health.

Hepatitis Transmission Via Fecal-Oral Route

The failure of nurses in a Chicago orphanage to properly wash their hands after each change of infant diapers was a major source of infectious hepatitis in one of the classic institutional outbreaks.

Most of the essential epidemiological points gleaned from that outbreak were discussed by Joseph Stokes, Jr., M.D., professor of pediatrics of the School of Medicine of the University of Pennsylvania. In outlining the epidemic, which pointed to the fecal-oral route of transmission, he reported the following:

Peculiarly, the disease seemed to appear only in new student nurses shortly after they began their training and did not seem to appear in the children or other adults at the institution. The knowledge of the presence of the disease there since 1942, and the fact that new interns also had begun to contract the disease, began by 1948 to deter new interns and nurses from applying for admission.

Gamma Globulin Injected

After November 7, 1948, gamma globulin was injected as a palliative and diagnostic measure into all new student nurses upon admission. Just prior to that date, 42 of 144 incoming students had developed jaundice soon after admission. In the 36 nurses who received the gamma globulin injections no jaundice de-

and early disease detection and treatment. He enjoys regular working hours, liberal off-duty periods, regular vacations with pay, and at times sabbatical leave for special training. The Health Insurance Plan of Greater New York (HIP) is also considering a retirement program for all participating physicians, he reported.

Dr. Baehr continued that under HIP 30 such medical groups, comprising almost 400 family physicians and 550 specialists, now provide comprehensive medical care to 400,000 persons in New York City. Since 90 percent of the participating families have selected a permanent family physician whom they may use regularly without financial deterrents, he felt that a far more favorable opportunity exists for an intimate and continuing doctor-patient relationship than in "sole" fee-for-service practice among similar low or moderate income families.

"Perhaps the most significant experience with group practice under HIP," he concluded, "has been the growing awareness among the group directors and specialists that the family physicians are the keystone of this type of practice and that the quality of medical care which they provide determines the reputation and the growth potential of the medical group."

Baltimore Program Relies On Community Practitioner

By uncovering multiple instances of unsuspected disease and by restoring clients to the point of employability, the Baltimore City medical care program is sound public health and an economic advantage to the community, according to George W. Dana, M.D., director of the medical care clinic of The Johns Hopkins Hospital. The program, instituted in 1947, endorsed by the Baltimore City Medical Society, and financially supported by the State

legislature, provides continuous medical service to persons maintained by Baltimore's Department of Public Welfare, he said.

Dr. Dana told the joint session that the program, which is under the authority of the commissioner of health, affords the client his own participating medical practitioner, an affiliating hospital, and free drugs.

Clients, in family units, are assigned to an affiliating hospital having its own complete medical care clinic and are given initial medical examinations, Dr. Dana stated. The clinic routinely forwards clinical reports to the client's physician and provides consultative and laboratory services at his request. Currently, the 24,500 Baltimore clients are receiving medical care service from 300 participating physicians, 59 of whom carry an assignment of 100 persons or more, he reported.

The community practitioner is the central figure in the program's concept of medical supply, Dr. Dana continued. Participation is voluntary and available to all Maryland

licensed practitioners. A physician expresses his interest to the medical care clinic directors of affiliating hospitals with which he desires association. He is paid under the capitation fee system at the rate of \$7 per client per year, providing home and office care at an average of 2.4 services per client per year.

Schools Can Educate For Useful Service

With "a broader concept of preventive medicine as to its environmental and social aspects, the medical school will more completely fulfill its function and responsibility in meeting the realities and demands of medical practice for today and tomorrow," Walter L. Bierring, M.D., commissioner of health of the Iowa State Health Department, told the joint session.

Because the practicing physician today works in his office or in the hospital more than in the home, he

Preventive medicine as practiced by the general practitioner is not limited to his office; it is found wherever he goes—in his daily practice, in his postgraduate studies, and in his civic activities through his community health council. Each decade preventive medicine occupies more of the general practitioner's time.

Without the cooperation of the general practitioners of America any preventive medical program, whether national, State, or local in character, is doomed to failure. Practicing physicians look to public health officials for leadership.

The general practitioner, however, should be led, not pushed. Continuous education is the key.

Public health is a specialty. Few general practitioners have the time or the training to do a good job in part-time public health work. Organized public health units with full-time personnel constitute the essence of good health protection.

—J. S. DeTar, M.D., Milan, Mich., speaker, House of Delegates, American Academy of General Practice; president, Michigan Health Council.

is no longer as familiar with the hereditary, family, home, personal, and economic environment of his patients as in the past and cannot judge the importance of these factors in relation to disease, Dr. Biering said.

The result, he said, is that social workers and agencies rather than physicians are most concerned with the environmental and social implications of health. Therefore, he maintained, the general physician should be taught the importance of understanding the civic activities related to medicine, problems of school health, maternal and child health, family life, and environmental influences, not only that he may be more useful to his patients, but that he may serve his community throughout his professional life.

During the past half century great and beneficial changes have taken place in scientific investigation, medical practice, and specific curative medicine, the physician continued, and these changes have resulted in a corresponding evolution in methods of medical education.

Medical Education

Undergraduate medical education should not only lead to the best care of the sick, the prevention of disease, and the promotion of health, Dr. Biering went on, but should also provide opportunity for developing and using knowledge of medicine as a whole through integration of basic and clinical sciences, wider application of clinico-pathological conferences, and greater emphasis on preventive medicine. Specialist training should be postponed to the graduate years.

In addition to the problems of preventive medicine, which include occupational diseases, malnutrition, maladjustment, psychoneurosis, social deficiencies, and health education, Dr. Biering said, long-term or chronic diseases are now a large part of general practice.

"Advancing the Frontiers of Public Health"

Health officers, public health nursing, medical care, and industrial hygiene sections of the APHA joined to present a "Joseph W. Mountin Memorial Session" in

Cleveland. The texts in full are published in the January 1953 issue of the American Journal of Public Health. Excerpts from the texts follow.

Introduction

By Leonard A. Scheele, M.D.,
Surgeon General,
Public Health Service

"Six months before his death, Dr. Mountin participated in a symposium on the Arctic Health Research Center at a general staff meeting of the Public Health Service. His opening sentences may be taken as an epitome of his major contribution to public health.

"It might seem incongruous," he said in that deceptively hesitant manner we knew so well, "that at the last staff meeting I appeared before you as an apologist for the aging and made a point of identifying myself with that group; now, 2 weeks later, I come again as an Arctic explorer. That incongruity is something I would like to make a point of."

"Everyone who knew Joe Mountin would like to make a point of the amazing diversity of his interests. He might call it 'incongruity,' but the ripe fruit of his brilliant mind was this very recognition that whatever affects the health of man is the proper study and a proper field of public health action. With recognition went his complete identification with the problem. Joe Mountin had in a very real sense the curiosity and instant response that Judge Learned Hand has called 'magnificent meddling': the force that drives man onward in his quest for mastery of the world he lives in."

Health Practice, Harvard Uni-
versity School of Public
Health

"Joe Mountin's great contributions . . . were based on sound knowledge of health problems derived from a long and rich first-hand experience at all levels of government, and on certain personal qualities which characterized him. . . . His contributions in public health administration stemmed from a broad, dynamic, progressive concept of 'health' . . . [which] must depend on differences in time, place and problem. . . . He kept asking: How well suited is the orthodox program of health departments to the needs of the people? What role is the department willing to occupy in areas beyond its traditional interest? How well equipped are public health groups to carry such additional functions as they may be called upon to discharge?"

"The history and development of local health units was well known to him, and many years ago he stated certain principles which should govern the organization of such units. . . . The governmental health department was of paramount importance in Mountin's eyes . . . the focal point of the community's health activity. It should contain the special perspective and the wealth of competency to be able to perceive the need; and it should have the

ability and the courage to take whatever action is necessary. . . .

"He did not conceive of the health department as doing the total health job . . . [and] although the health department should definitely not engage directly in all kinds of health activities, it should find ways to participate in each type. . . .

"Mountin appreciated the importance of understanding the private practitioner's problems and finding methods of work with him. . . . With increasing extension of public health activities into the field of personal health services, particularly in chronic disease control, he realized the importance of not going too fast and of carefully working out professional relationships. . . . If health departments were to do their job properly, Mountin thought they would need to work very closely with hospitals and other agencies providing medical care. . . ."

Chronic Disease and Aging

By Vlado A. Getting, M.D.,
D.P.H., *Commissioner, Massachusetts Department of Public Health*

"It is almost impossible to review the development of any program in public health in the past score of years without finding Joe's guiding hand somewhere in its development. He brought out the need of health departments to evaluate their programs carefully, to consider the characteristics of the total population they serve, saying that health is positive and that public health responsibility must be geared to promoting ever higher standards of human efficiency and satisfaction. . . . He reminds us that there has been phenomenal progress in the development of programs for children, and he suggests that the same type of approach as was used in studying the child and his needs is now needed for the mature and older members of the community. . . .

"While Dr. Mountin stimulated not only health departments but also

voluntary agencies to assume a vital role in the development of a community program for older people, he indicated that such a program must be a community program shared by all. . . . If the health department develops an understanding of the problems of the aged and arouses community interest, he was convinced that the health department need do only a small fraction of the total program itself, and that the community as a whole will awaken to its responsibility. . . ."

Regionalization

By John B. Grant, M.D., *Associate Director, Division of Medicine and Public Health, The Rockefeller Foundation*

"Joe Mountin's chief characteristic was the embodiment in his philosophy of a comprehensive horizontal rather than a vertical specialized approach to problems of public health. And another characteristic over the years was the manner in which earlier general principles were later amplified in detailed recommendations. . . .

"Organization is the cornerstone required for the advance of any frontier of public health. . . . Mountin considered that multiplicity of agencies was the chief evil to be attacked. The summation of his thinking was that this evil required regionalization under a single administration for its removal. His guiding principle was that enunciated by the British Ministry of Reconstruction in 1919: 'The first principles of good administration require that when a special function is to be undertaken, it shall be undertaken by one governing body for the whole community needing the service, and not for different sections of the community by several governing bodies.'

"The level of health services of the nation in 1975 will be proportionate to the degree that Mountin's recommendations are implemented

for integration of all services through regionalization under a single administration."

Medical Care

By Franz Goldmann, M.D.,
Associate Professor of Medical Care, Harvard University School of Public Health

"With creative imagination and common sense he crusaded for the continued adaptation of medicine to social needs and uses, and he had the courage to state and defend unorthodox views at a time when many others were aloof, if not hostile, to any proposal implying a change from chance to choice. Knowing that truth does not necessarily conquer by itself, he was untiring in interpreting new ideas against the background of historical developments. . . .

"Mountin frequently expounded each and all of the rules of sound administrative organization [democratic, simple, and inexpensive] and used every opportunity to make them living facts in the administration of tax-supported health services. . . . Mountin did not confine his interest to technical matters and questions of methodology. He gave much thought to some of the concepts guiding contemporary health policy and, especially, the theory of separation of preventive and curative health services. . . . [and] was confident the blending of preventive and curative service could be achieved through a complete health program. . . .

"Mountin fought under the flag of faith embroidered with the words: 'Let the welfare of the people be the supreme law.' He never wavered under the fire of those drawing together around the flag of fear. By taking such a stand he acted in conformity with George Washington's maxim: 'Let us raise a standard to which the wise and honest can repair.'"

Field, Laboratory, and Legal Approaches to Treponemata

Reports of new data and new approaches to the syphilislike diseases, yaws and pinta, a review of a laboratory evaluation-guidance program, and a suggestion for reevaluation of premarital blood test laws were heard by APHA members attending the laboratory and epidemiology sections, and by the Conference of State and Provincial Public Health Laboratory Directors.

Pilot Study Should Precede Mass Treatment of Yaws

In treating yaws, a house-to-house canvass where everyone would be subjected to clinical, anamnestic, and serologic examinations would be ideal but is often impossible, impractical, or too difficult, said Charles R. Rein, M.D., associate professor of clinical dermatology and syphilology, New York University-Bellevue Medical Center, New York City.

Any treatment campaign based solely on clinical examination, he said, is limited because persons in the incubation stage of yaws are missed if no clinical manifestations are evident, and it is impossible to detect the seropositive asymptomatic latent yaws patients who ultimately may develop cutaneous relapses, thereby setting up new infectious reservoirs. Also there will be included some nontreponemal disease that will respond to penicillin therapy, thereby causing a fallacious increase in cures. Some nontreponemal conditions which do not respond to penicillin will result in a fallacious decrease in cure rates, Dr. Rein cautioned.

"The number of patients with nonvenereal conditions subject to penicillin therapy would depend on the diagnostic acumen of the clinicians," he said.

Dependence on anamnestic evidence is also fraught with difficulties, he said. "The word soon gets around among natives that they will receive some 'magic medicine' if they state that they have had yaws, and this they will gladly do with the hope that it will cure their bone pains, malaise as well as many imaginary ills."

Serologic Survey

A house-to-house serologic examination would be slow. The interval between serologic survey and institution of treatment would require several days. Some individuals requiring therapy would not be available when treatment teams revisited the houses. This type of survey, Dr. Rein emphasized, would require extensive laboratory facilities to examine the large number of blood specimens and well-trained serologists to evaluate results.

Dr. Rein quoted Dr. H. J. Magnusson as comparing the problems of combating yaws with those in shooting down attacking enemy planes: It is foolish to fill the sky with flak to shoot down one or two planes. Precision-aiming mechanisms, accurately controlled and well-manned, are needed.

It may be feasible to treat entire populations in high prevalence areas without regard to serologic examinations, Dr. Rein explained, but careful serologic examinations with tests known to have high levels of sensitivity and specificity are greatly needed in low prevalence areas. "To date, the filter paper method and the various modifications of the Chediak reaction have not been proven to be of

sufficient sensitivity and specificity as compared to the standard tube or slide tests performed on serum. While the use of capillary tubes for collection of specimens has been found satisfactory in the United States, this would not be a practical approach to the yaws problem," Dr. Rein added.

A simple, inexpensive and yet consistently effective serodiagnostic procedure is greatly needed in low prevalence and underdeveloped areas with inadequate laboratory facilities and insufficient trained technicians, he noted.

Limitations

Without an awareness of the limitations of serodiagnostic procedures in mass treatment campaigns, errors of omission and commission will arise, the syphilologist warned. These chief limitations are false negative reactions, false positive reactions, and seroresistance.

A pilot group with a well-controlled laboratory set up as soon as possible, and preferably before mass therapy is instituted, is important whether or not serodiagnostic procedures are to be employed. Dr. Rein stressed, for it is during the demonstration, survey, and training phase of the pilot program that the laboratory can supply information of value during the later expansion and consolidation of the campaign.

This information should include, he said, darkfield disappearance time following therapy to determine the immediate efficacy of the penicillin preparation to be employed, quantitative serologic tests to note the serologic trend following therapy, and differentiation between relapse and reinfection.

Would Preassess State Laws On Premarital Examination

The marked decrease in the number of syphilis cases reported in recent years, especially infectious syphilis, calls for a reevaluation of

the premarital examination laws as a case-finding and control technique, two California health officials believe.

Philip K. Condit, M.D., and A. Frank Brewer, M.D., of the division of preventive medical services, California State Department of Public Health, offered California's experience during the 12 years, 1939-51, as an indication of what the tests accomplish.

8,100 Cases Since 1939

In California, more than 2 million persons have had premarital blood tests for syphilis since 1939. The tests required by State law discovered 8,100 cases of previously unknown and untreated syphilis, 510 of them primary and secondary syphilis, and about 3,000 in need of further treatment.

Finding infectious syphilis cases and bringing them to treatment to prevent transmission from one marital partner to another to the child is the first objective of the premarital law, Dr. Condit and Dr. Brewer pointed out. Treatment of the other cases discovered fulfills another objective by preventing further progression and disability.

The case-finding returns, however, are diminishing, they found. The number of syphilis cases reported from all sources in California declined 63 percent from 1946 to 1951 for all forms, and 88 percent for primary and secondary syphilis.

Ratio of Infections

Attending the decline in syphilis prevalence is the smaller number of cases discovered by premarital tests, the doctors found. From 1949 to 1951 the ratio of infections to persons tested decreased from 1 in 437 to 1 in 553 for all forms.

The ratio for primary and secondary syphilis decreased by more than 50 percent—from 1 in 2,168 to 1 in 4,836. Thus, the unit cost per case of this type discovered more than doubled during the 3 years, they noted.

In actual numbers the score for

the 3 years stands: premarital examinations, 511,100; all syphilis cases discovered, 1,079 (primary and secondary, 162). Thus a total of the cases found by the premarital tests constituted 3.4 percent of the State total; 32,315 cases were reported from all sources in the State.

Although the 162 infectious cases found was proportionately small, the doctors called attention to the fact that an indeterminate number were prevented by the premarital tests, which served to get medical supervision and treatment for the infected individuals.

Indiana Rates Performance Of Laboratories in State

The goal of a laboratory evaluation-guidance program is to assure in the interest of public health, the best possible service to medical practitioners, Paul Fugazzotto, M.S.P.H., Ph.D., chief serologist of the bureau of laboratories, Indiana State Board of Health, told the Conference of State and Provincial Public Health Laboratory Directors.

The policy of the State health department must be one of active interest, he continued, and the participating laboratories should feel that the health department, or reference center, will guide and help whenever needed. A program that guides rather than polices, and that assists the laboratories to solve problems, is the most desirable, he felt.

Volunteer Participation

In Indiana, Dr. Fugazzotto reported, such a program has resulted in 50 laboratories participating on a volunteer basis, in addition to the 67 approved for making premarital and prenatal serologic tests for syphilis.

Technical phases of the Indiana program, he said, include checktesting of clinical specimens, distribution of control serums, study of reagents, consultation service to laboratories, including the checking of environmental temperatures at which test

reagents are stored and used, review of general techniques and equipment used, and evaluation of serologic test performance.

Deficiencies in test performance of a participating laboratory should be diplomatically but specifically called to its attention, Dr. Fugazzotto continued, with explanation of possible cause and suggestions for remedy or improvement. Technicians often feel that their test performance is not entirely satisfactory and are glad to be told why and what to do about it, he stated.

Causes of Difficulties

Only visits from a trained serologist will discover the cause of most difficulties, the speaker said. Some of these difficulties are due to environmental conditions or failure to follow test specifications, he said, but others are caused by intangible factors which are not described in the literature and "the technician needs someone to tell him where he has failed to consider such factors."

Visual Tests Adequate In Pinta Mass Survey

Pinta may be diagnosed with sufficient accuracy for mass surveys by examination of exposed surfaces of the body, reported Walter F. Edmundson, M.D., associate director, and Sidney Olansky, M.D., director of the Venereal Disease Research Laboratory, Public Health Service, Chamblee, Ga., and Arnoldo Lopez Rico, M.D., chief of the Center of Epidemiological Studies, Rural Cooperative Medical Service, Apatzingan, Michoacan, Mexico. They based their conclusion on clinico-serologic surveys conducted by the Center of Epidemiological Studies in four communities in the Tepalcatepec Basin in Mexico.

The evidence from these surveys indicates that "latent" pinta must be very uncommon, the speakers

stated. Only 4.64 percent of 194 children, 16 years of age or less, clinically diagnosed "no pinta," had either positive or doubtful serologic reactions. In three of the villages, only 2.76 percent of 145 children had reactive serologies. Special efforts were made to study children, Dr. Edmundson and his colleagues explained, in order to differentiate serologic results caused by pinta from those caused by syphilis since pinta is usually acquired in childhood and syphilis, known to be common in the area, in adolescence or later.

The "No Pinta" Group

Of 348 persons of all ages clinically diagnosed "no pinta," 14.37 percent had reactive serologies, the investigators reported. The assumption can logically be made, they maintained, that these reactions were syphilitic reactions, "biological false positives," or residual seroresistance following adequate treatment of pinta. Although the persons in three of the villages were queried as to previous treatment with penicillin or arsenicals, the reliability of their answers is questionable since many of the patients with pinta seemed to feel that an admission of previous treatment would injure their chances of additional medication.

The speakers pointed out also that it is known that lesions of pinta may occur only on unexposed surfaces of the body in about 1 percent of the cases, but they believe their occurrence is probably rarer statistically than the other causes of reactivity mentioned.

Although pinta does not generally cause disabling or killing effects, this disease deserves large-scale control efforts by the nations in which it exists, concluded Dr. Edmundson and his co-workers. The disfigurement caused by the disease interferes with personal freedom and with the development of a healthy outlook on life, they stated. Freedom of choice as to place of habitat, employment, and selection of a mate is drastically curtailed by affliction with pinta.

Professional Training for Pediatricians and Nurses

The well child conference is being used as a key element in the pediatric training of medical students at the University of Washington and in the pediatric residency at the University of Pennsylvania, it was reported to the maternal and child health, public health education, and public health nursing sections.

During a session on "professional education in public health," reports were also heard from Detroit concerning the use of monthly discussion meetings which bring together public health nurses from the health department and maternity service nurses of the hospitals.

The Philadelphia project they described included these features:

Assignment of residents in pairs to the same weekly conference throughout their 2-year training period.

Selection of cases which afforded opportunity for long-time study.

Limitation of appointments for each resident to four during a 2-hour session.

Informal discussion of the cases between the resident and supervisor at each session.

Assignment of a member of the university teaching staff to each session.

Conferences among the supervisors for discussion of the program.

Materials and Evaluation

Materials used in conducting the health conferences included, in addition to the usual medical record form, a sheet on which was noted the development of motor skills and a yearly summary of the child's progress from the first through the sixth year, and a newly designed health record booklet in which notes as to diet, vitamins, and next appointment date were made by the physician and notes of the child's progress and questions to bring up at the next conference were made by the parent.

Evaluation of the program, important to the success of any program, they said, has been obtained from both the supervisors and the pediatric residents. Typical of the supervisors' comments quoted was this one: "It is extremely valuable to have residents involved in this experience while they have access to counsel and expert advice from the staff. It creates interest in good preventive pediatric care. . . . It is a definite contrast to the classic teaching experience with specific

Child Health Program Trains Pediatricians

A public health department pediatric training program in connection with its child health program was suggested by Elizabeth Kirk Rose, M.D., and John A. Rose, M.D., as a possible solution to the problem of including experience with normal children in the pediatric residency curriculum. Dr. Elizabeth Rose is chief of the division of child hygiene, Philadelphia Department of Health, and assistant professor of pediatrics, University of Pennsylvania, and Dr. John Rose is assistant professor of psychiatry at the university.

Child health conferences, they noted, provide a group of normal children who can be seen regularly over a number of years. The organization of a training program for pediatric residents in connection with these conferences requires, however, that provision be made for adequate supervision of the residents' work.

diseases. . . . It demonstrates variability of normal growth and development." Questionnaires circulated among the residents revealed "unanimous approval of this opportunity to associate with well children," they reported.

Nurse Sessions Improve Hospital Maternal Care

Periodic discussion meetings by maternity nursing supervisors and other interested hospital and public health personnel have contributed significantly to the improvement of maternity and infant care facilities and procedures in Detroit hospitals and to a better prepared maternity personnel, reported Garner M. Byington, M.D., Dr.P.H., maternal, child and school health director of the Detroit Department of Health.

Subjects discussed at the meetings included: over-all maternal and child health programs; maternity hospital rules and regulations; venereal disease problems relating to mothers and infants; proper formula sterilization; incubators and their operation; hand-washing facilities; and general cleaning of nursery space. To promote an improved nursing service, copies of the American Academy of Pediatrics' "Standards and Recommendations for Hospital Care of Newborn Infants—Full-Term and Premature," were provided to hospitals lacking them.

Expectant Parent Classes

Since prevention of premature births and the early care of premature infants are of major importance, continued Dr. Byington, classes for expectant parents were established in several hospitals. Postpartum classes have been started also by a few nursing supervisors.

In discussions with hospital and public health personnel the availability of a city ambulance to transport premature infants to properly equipped hospitals was stressed, and approved methods of

preventing infection, correct feeding, providing heat while the baby is in the delivery room, and maintaining heat upon removal to the nursery were discussed.

Dr. Byington stressed the value of the exchange of information and views between hospital and public health personnel. By public health nurses being informed of improved hospital methods, he said, they then are able, in their home visiting, to promote the acceptance of newer techniques of perineal care and the elimination of cord dressings and umbilical bands among mothers who, having had other babies, might resist the "drastic" changes.

Complete Care Accented In Pediatric Training

A complete program of care is accented at the University of Washington's child health center where pediatric training is received by the medical students, reported Robert W. Delsher, M.D., associate professor of pediatrics and director of the center.

Teamwork features the services of a medical social worker, public health nurse, nutritionist, dental hygienist, dentist, psychologist, and psychiatrist as well as pediatrician, he asserted. Conferences with the mother and evening visits to the child's home are included for the student, who may also call on any of the staff when necessary. Also, he visits a preschool nursery. Staff conferences which are moderated by the psychiatrist are also held.

Many students think at first that a well child conference is a health department function. They spend 40 to 45 carefully allotted hours at the center and are able to see the interrelationships of some of the basic principles of pediatrics, public health, and psychiatry. They grasp the functions of each member of the staff as well as what phases other than the physical are significant in following a child's growth and development, he said.

RN-PHN Group Discussion Produces Better Service

In addition to improvement of nursing care of mothers, one real benefit from the monthly meetings of the maternity nurses of metropolitan Detroit is the better understanding and friendship developed among nurses, said Irene Nelson, R.N., director of education at the Women's Hospital in Detroit, Mich.

Encouraged to attend the group sessions are all nurses, students, and others interested in obstetrics, but regular notices are sent to nurses in charge of the obstetrical departments in metropolitan hospitals, the State hospital nursing consultant in the area, and nurses from the nursing division of the Detroit Department of Health and the Visiting Nurse Association.

"The public health nurses attending the meetings are now our friends, and we call upon them when questions or problems arise. I am sure that we had as many questions and problems in the past, but we hesitated, not knowing whom to contact in the public health agency. These meetings are held in different public health stations or centers and hospitals in the city. Tours are arranged so that nurses have a chance to see and learn about the public health facilities and various hospitals," the speaker reported.

Common Understandings

The meetings afford an opportunity to explain changes in hospital techniques, she said. Before these meetings were held, mothers were told by some that babies did not need abdominal binders, although previously they had been told by others that binders were necessary. "We can only decrease a mother's fears and anxieties and make our teaching effective when we teach the same things," she pointed out.

Part II of This Special Section
Will Appear in Our February Issue.

Nursing in Venereal Disease Control—A Suggested Guide

During the past few years there has been a dramatic change in the venereal disease problem in the United States. Control activities have reduced the incidence of syphilis and with newer treatment schedules, therapy can be carried out in clinics or in the offices of private physicians. However, special venereal disease centers are still needed. These changes require the application of new skills and techniques. This is particularly true of the public health nursing services which will more and more be called upon to assume responsibility for participation in venereal disease control activities.

In response to the expressed needs of health departments, this publication has been prepared as a guide in planning for nursing service in the community in relation to venereal disease. Developed by the nursing branch, with guidance from the medical staffs of the Division of Venereal Disease and the Division of Public Health Nursing, it covers the venereal disease program, public health nursing in the venereal disease program, the clinic, and an evaluation.

The section on nursing includes a discussion of the nurse's responsibilities in case finding, health education, and care of the sick; and the principles, functions, and content of the patient interview. Physical facilities, equipment, and clinic procedures are considered in the third section, as well as follow-up activities in the clinic and in the field.

Nursing in Venereal Disease Control. A suggested guide. (Public Health Service Publication No. 198) 1952. 27 pages. 15 cents.

Financial Status and Needs Of Dental Schools

Dental education, in common with all other fields of higher education, has felt the impact of accelerating scientific progress and economic change. It is confronted today with the complex problems of maintaining high standards and meeting increasing demands in the face of costs and backlogs of need for space and equipment. In recognition of these urgent problems, the Council on Dental Education of the American Dental Association asked the Public Health Service to undertake an intensive study of the financial status and needs of schools of dentistry.

This report, parts of which were summarized in the October issue of *Public Health Reports*, covers the 40 American dental schools in full operation during 1949-50. The study analyzes faculty resources, operating expenses, separately budgeted research, postgraduate instruction, sources of income, and unmet needs for staff and facilities. Information on operating expenses and income of the 18 schools of dental hygiene in operation during the same period is also included in the report.

Financial Status and Needs of Dental Schools. (Public Health Service Publication No. 200) 1952. 83 pages; tables, charts. 25 cents.

Distribution of Health Services in the Structure Of State Government

Part Two—General Services and Construction of Facilities for State Health Programs

"Distribution of Health Services in the Structure of State Government" is the subject of a decennial study made by the Public Health Service for the purpose of presenting a picture of total State organization for the provision of health services. The data for the 1950 survey are being published in four parts,

the first of which, "Administrative Provisions for State Health Services," was reviewed earlier. Parts three and four will cover personal health services and environmental health and safety services.

Part two is concerned with the organization, policies, and practices for the provision of general supportive services and construction of facilities for State health programs. The first section is a discussion of the methods by which State agencies supply general technical services which contribute to several of the specialized health programs. Because of the interrelationships among programs, these services have been treated separately, although they do not develop independently, but as parts of the specialized programs which they support.

Another State activity of importance in the total health picture is the program for expansion and improvement of hospitals and health centers. This forms the second section of the discussion, which gives the status of hospital construction programs administered by the hospital authorities of each State and Territory, the District of Columbia, Puerto Rico, and the Virgin Islands as of December 31, 1950.

Mountain, Joseph W., Flook, Evelyn, and Mullins, Rubye L.: *Distribution of Health Services in the Structure of State Government 1950. Part Two, General Services and Construction of Facilities for State Health Programs.* (Public Health Service Publication No. 184, Part Two) 1952. 117 pages; tables. 35 cents.

Publications for which prices are quoted are for sale by the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C. Orders should be accompanied by cash, check, or money order and should fully identify the publication (including its Public Health Service publication number). Single copies of most Public Health Service publications can be obtained without charge from the Public Inquiries Branch, Public Health Service, Washington 25, D. C.

Effect of Fluoridated Public Water Supplies On Dental Caries Prevalence

By FRANCIS A. ARNOLD, JR., D.D.S., H. TRENDLEY DEAN, D.D.S.,
and JOHN W. KNUTSON, D.D.S., Dr.P.H.

SUBSEQUENT to the epidemiological and experimental findings that the use of fluoride waters reduced the prevalence of dental caries, a number of studies were undertaken to evaluate the effects of adjusting the fluoride levels of public water supplies to an optimum concentration, about 1 ppm of fluoride (F). Preliminary and annual reports from these study areas have appeared in the literature from time to time during the past 5 or 6 years (1-9). Essentially, the findings of all these studies are in accord although each has its individual characteristics from a procedural standpoint.

The present paper reports in more detail than a preliminary report (1) the methodology and results of one of these studies, namely, the Grand Rapids-Muskegon study, and includes the results obtained after 6½ years of fluoridation of the Grand Rapids water supply.

Selection of Study Area

Because much of the background data regarding the effects of fluoride waters on dental

caries was obtained in the north central part of the United States, this general area was selected for the fluoridation project. The choice was further influenced by the fact that (a) a considerable amount of data had been obtained on children who had used domestic water supplies for which Lake Michigan was the source, and (b) all evidence suggested that this general area had a high dental caries experience rate (10). Following a careful survey of a number of communities in this area, and with due consideration of the numerous details which influence a project of this sort, the city of Grand Rapids, Mich., was selected for the primary study area. The city of Muskegon, Mich., which has the same source of water and similar treatment procedures as Grand Rapids, was chosen as a control area. To establish what might be termed an "expectancy curve" for this study, a natural fluoride area, the city of Aurora, Ill., was selected. The Aurora water supply contains 1.2 ppm F and has a reliable history of constancy back to 1895 (11).

Base-Line Examinations

Dental examinations were started in Grand Rapids in September 1944. Four trained dental officers performed the examinations in selected schoolrooms, using mouth mirrors and explorers, and standard type examining lights. The examining equipment throughout the study has been a double-end SSW No. 3 explorer and standard plain mirror. The source of light has been a standard E. E. N. T. examination lamp.

Dr. Arnold is associate director in charge of research and Dr. Dean is director of the National Institute of Dental Research, National Institutes of Health, Public Health Service. Dr. Knutson is chief dental officer of the Public Health Service.

Cooperating with the Public Health Service in this study are the Michigan Department of Health and the University of Michigan.

Bite-wing X-ray examinations were made of a representative sample of children examined by the different examiners to evaluate, in part, the "examiner error." The result of this evaluation will be the subject of another report. A complete oral examination was made and a residence history obtained, which, for the younger children, was verified by a questionnaire signed by parent or guardian. Only the principal dental findings will be considered here.

The examiner dictated his findings in code to recording scribes. The code used for recording dental conditions is similar to one described previously (12). It is designed to give a complete description of the health status of all teeth and each surface of individual teeth, both separately and collectively. A short "indoctrination" period was used to acquaint the examiners and scribes with the code and to establish consistency among examiners regarding the sub-

jective assessment features of diagnosis. Virtually all pupils of the school systems of the selected cities were examined, including nursery schools and junior college students where available.

Subsequent Annual Examinations

Following the original "prefluoridation" examinations, annual dental examinations have been made in Grand Rapids and Muskegon. These examinations are being conducted in the same manner as were the original ones. There have been changes in dental examiners with the exception of one officer who has participated in each series of examinations. Each new examiner has been calibrated against this one officer to standardize diagnostic criteria.

These annual examinations are made at the same time each year (October and November)

and are performed on selected samples of the school children. This annual study sample was selected after careful review of census data and consultation with city planning department officials. On the basis of available information, the 31 school districts of Grand Rapids were classified on a socioeconomic basis. From the 79 schools in these districts, 25 representative schools were selected, and the examiners were assigned schools on a basis of equal-sized samples of comparable population groups. In Muskegon, the annual examinations have been conducted in almost all schools, excluding only a few small schools on the periphery of the city where many students are from rural areas. The examiners work in the same schools each year. Each new examiner is assigned the schools which had previously been assigned to the examiner whom he replaced.

Selected age groups of children are examined within each of the schools. Selection is made on the basis of school grade or class, using all children present in a class or grade of a school. Choosing examinees by grade in this manner will, in some instances, not give well-distributed specific age groupings. For example, an eighth-

grade group will give a well-distributed 13-year-old age group, and will include the older 12-year-olds and younger 14-year-olds when specific age groups are based on age at last birthday. The number of grades included in the 1951 examinations give well-distributed age groupings through the 13-year-old groups.

Each child in a selected grade or class is examined regardless of his residence history. The examiner has no knowledge at the time of examination whether or not the individual examinee is a "continuous resident" of the city in which the examinations are being held.

The following table shows the grades, or selected class groups from these grades, which were included for each annual (fall) examination in Grand Rapids and Muskegon subsequent to the original or basic examinations:

Year	Grade or class
1945-----	Kindergarten, 1, 8
1946-----	Kindergarten, 1, 4, 8
1947-----	Kindergarten, 1, 4, 8, 11
1948-----	Kindergarten, 1, 4, 8, 11
1949-----	Kindergarten, 1, 4, 6, 8, 11
1950-----	Kindergarten, 1, 2, 3, 4, 6, 8, 11
1951-----	Kindergarten, 1, 2, 3, 4, 6, 8, 11

¹ Decayed, extraction indicated, or filled deciduous teeth. A decayed and filled tooth is counted only as a filled tooth.

² The 1944-45 basic examinations in Muskegon were not done until late spring of 1945; therefore, no repeat examinations were made in the fall of 1945.

In addition to the routine dental examinations in these two cities, special studies, including bacteriological and chemical studies of the saliva, are being made on selected groups of children. The results of these studies will be reported at a later date.

Fluoridation

The addition of sodium fluoride (NaF) to the Grand Rapids water supply started in January 1945. Since that time, the people of this city have been ingesting a water with a fluoride content of 1 ppm F. Daily analyses show that this concentration has been maintained within a 0.2 ppm range (13). No significant mechanical difficulties of any consequence have been encountered. Also, in the course of 7 years of fluoridation, no established complaints of any

ill effects have been encountered from the numerous manufacturing and processing concerns, nor from the population involved.

The water supply at Muskegon remained unchanged until July 1951, when this city started adding fluorides to its water supply.

Results

Base-line data were obtained on the oral health status of 31,007 Grand Rapids residents aged 2-24 years, 8,304 Muskegon residents aged 4-25 years, and 8,811 Aurora, Ill., residents aged 4-20 years. The present report includes only the findings in regard to dental caries in "continuous resident" children aged 4-16 years. This selection excludes the results on children of these ages who have lived outside their respective communities for more than 3 months in

any one calendar year. Table 1 shows the number of continuous resident children of these ages examined each year and their distribution by age.

For purposes of comparison, the results of oral examinations of Aurora school children are shown in table 2. As mentioned previously, the results at Aurora represent the caries experience in children who have used water containing 1.2 ppm F throughout life. It is this same caries experience that one might expect to find in the teeth of Grand Rapids children after fluoridation has been in progress a comparable period of time in respect to the specific age group under comparison.

It should be noted that the dental examiners in this study obtained similar results to those

findings previously reported in the basic epidemiological studies for 12-14-year-old children of Aurora, Ill. (11).

The amount of dental caries experience observed at each examination in the deciduous and permanent teeth in both the study and control areas is shown in tables 3 and 4. There has been a reduction in the amount of dental caries observed in the Grand Rapids children subsequent to fluoridation of their water supply. For example, comparison of the 1951 and 1944-45 findings on permanent teeth shows this reduction to vary from 66.6 percent in the 6-year-old children to 18.1 percent in the 16-year-olds (table 4 and fig. 2). A similar comparison of results at Muskegon shows the percentage reduction to range from 1.5 percent in

¹ Decayed, missing, or filled.

² The 1944-45 basic examinations were done in the fall of 1945.

A decayed and filled tooth is counted only as a filled tooth. were not done until the late spring of 1945; therefore, no repeat

6-year-olds to a high of 15.5 percent in the 11-year-olds. In Muskegon, the number of examinations was smaller, especially in the older age group. The 5-year-old group of 1951 is older by an average of 4 to 5 months than the same age group of 1944-45. Preschool children were examined in 1944-45, but in 1951 only children old enough for entrance to kindergarten were examined. It should be noted that the percentage reductions observed at Muskegon do not fit a consistent pattern as do those at Grand Rapids and may, in part, represent sampling error.

In establishing DMF rates, two portions of this rate are derived from observations based almost entirely on objective assessment, namely, the number of missing teeth and the number of filled teeth. Table 5 shows a comparison of the number of missing and filled permanent teeth

for the study and control areas. There has been a reduction in the average number of missing teeth observed in Grand Rapids children up to and including the 13-year-old age group. This situation did not prevail in Muskegon. The findings in regard to the average number of filled teeth in these two areas would not explain the reduction in missing teeth. There has been little change in the average number of filled teeth in Grand Rapids whereas in Muskegon this average shows some indication of having increased slightly in the younger age groups.

Discussion

The 1951 results in this report represent the findings of the seventh year of a study on the effect of fluoridation of public water supplies on dental caries prevalence. The results in

Grand Rapids for 1951 represent findings after 61½ years of exposure to a fluoride water environment. The tabular data indicate a definite reduction in age specific caries rates in Grand Rapids children. As shown in figures 1 and 2 the observed caries rates for Grand Rapids have changed over the past 6 to 7 years and in the younger age groups are approaching the findings on continuous resident children of Aurora, Ill., in 1945-46.

It is of special interest to note the increment in dental caries between ages 6 and 9 years. In Grand Rapids for this age period in the basic examinations, this increment was 3.123 DMF teeth per child as compared to 1.781 DMF teeth per child in the 1951 examinations. For Muskegon children, the basic examination results indicate an incremental increase between the years of 6 to 9 of 2.997 DMF teeth as compared to 2.717 as observed in 1951. Thus, the increment of dental caries over this 3-year-age period has decreased in Grand Rapids by 1.34 DMF teeth while at Muskegon the decrease is only 0.28 DMF teeth.

Attention is called to the fact that DMF rates in this age group (6-9 years) reflect mainly the caries rates in first permanent molars. In other words, the results to date on Grand Rapids children indicate that their first permanent molar teeth are decaying at a rate which is only 57 percent of the 1944-45, or prefluoridation,

Figure 1. Comparison of dental caries experience in deciduous teeth of continuous resident school children in Grand Rapids, Mich., and Aurora, Ill.

Figure 2. Comparison of dental caries experience in permanent teeth of continuous resident school children in Grand Rapids and Muskegon, Mich., and Aurora, Ill.

rate. Also, considering that only the 6-year-old and part of the 7-year-old children were born into a fluoride environment, this result is consistent with the findings for Aurora children.

It should be noted that the only known major change affecting the environment of these two groups of children over the period of study has been the fluoridation of the Grand Rapids water supply. There have been no concerted efforts to inaugurate any special caries control programs, such as topical fluoride programs, in either city since the study started. From an epidemiological standpoint the results of this study, together with those of other comparable studies, permit the conclusion that adjusting the fluoride content of public water supplies will result in a reduction of the incidence of dental caries in school children.

Summary

The methodology and results after 7 years of the Grand Rapids-Muskegon study have been described. The 1951 results on continuous resident children after 61½ years of fluoridation of the Grand Rapids water supply indicate:

1. There has been a reduction in dental caries rates in permanent teeth of Grand Rapids children ranging from 66.6 percent in 6-year-old children to 18.1 percent in the 16-year age group. Similar results have been obtained regarding the deciduous teeth.

2. Similar reductions have not been observed in Muskegon where the water supply remained

"fluoride-free" (<0.2 ppm F) until the last 3 months of this study period.

3. This change in dental caries rates at Grand Rapids was also reflected in observations based on objective assessment, that is, a reduction in the number of missing teeth.

4. A comparison of the 1951 caries rates in Grand Rapids with those of Aurora, Ill., shows that insofar as can be determined to date the use of a fluoridated water gives the same beneficial effects as does the use of a natural fluoride water of similar concentration.

ACKNOWLEDGMENT

The following dental officers annually take time away from their individual research projects to conduct the dental examinations in this study: Drs. Robert C. Likins, A. L. Russell, David B. Scott, D. E. Singleton, and Robert M. Stephan. The following dentists, formerly with the Public Health Service, participated in the study: Drs. F. S. Loe, Los Angeles, Calif.; H. B. McCauley, Baltimore, Md.; S. J. Ruzicka, Cleveland, Ohio; and Edwin M. Short, Hyattsville, Md.

The authors also acknowledge the assistance given by the superintendents of education, principals, and teachers of their respective cities. And they acknowledge the cooperation of the health officials in the cities involved in this study.

"We are in danger of building a Tower of Babel"

By VANNEVAR BUSH, D.Eng., Sc.D.

An eminent scientist speaks of overspecialization and the volume of publication . . . and proposes concrete action

EVERY SCIENTIST feels acutely today the effects of overspecialization. The volume of publication is so vast that it is impossible to keep abreast of it, even as the field of interest is narrowed. Whole new sciences and branches of engineering appear, with their specialized societies and journals. Intensely progressive gatherings of research workers develop their own jargon, unintelligible except to the initiated, heightening the barriers which separate their works from the main stream of progress.

Dr. Bush is president of the Carnegie Institution of Washington. As wartime director of the Office of Scientific Research and Development he was intimately associated with developments in nuclear fission and with the work of the Committee on Medical Research. Dr. Bush's address to the 23d annual Scientific Assembly of the Medical Society of the District of Columbia appeared in full in the January 1953 issue of the Medical Annals published by the Society. These excerpts are presented with permission of the editors and the author.

We are told that, long ago, there was a strange sort of real estate development. My memory of what I learned about it in my youth is somewhat hazy. But it seems that there was a project to construct some sort of Empire State Building, only much larger and more grandiose, reaching up toward the sky and mingling with the clouds. It was called the Tower of Babel. As the story goes, it was never completed, for the plans ended in confusion. The workmen suddenly found that each one was speaking a special language and that no man understood what the other was saying. So the minor construction went on piece by piece, but none of the pieces fitted; and the general plan of construction was completely lost. We are in danger, in science, of building a Tower of Babel.

The Complexity of Man

This is especially true in the science that deals with man. For man is complex, with a complexity far exceeding that which was assumed in the early days when the practice of medicine was a simple matter of applying empirical experience

and the science of medicine was nonexistent. As we have learned more, so have we learned that there is vastly more to learn before any comprehensive over-all understanding can emerge. A unitary organism has been found to involve the widest possible range of science, in the interconnected phenomena by which it functions to maintain existence in its environment.

Very subtle organic chemistry appears in connection with its hormonal system, its enzymes and vitamins, its antibodies, the nucleic acids of its genetic apparatus, and the metabolism of its proteins. A mysterious process by which a substance molds its surrounding medium into its own image transcends all that classic chemistry has to teach. In the chemistry of muscle, that process, unused by man in his artificial engines, whereby the energy of chemical combination is transformed directly into mechanical work without the intervention of any other forms, leads us into thermodynamic and chemical considerations beyond our present comprehension. The electrochemistry of nerve action introduces relationships far more bizarre than those simple effects which man utilizes in his batteries or his electrometallurgy.

And all this is affected, in completely ungrasped ways, by the functioning of a brain, which in its mere complexity reaches far beyond the relatively feeble electronic computing devices of which man is currently so proud, and which undoubtedly also involves phenomena the mere nature of which we cannot now specify or define, much less examine. The human system is unbelievably complex, and its examination by research calls for all the science that man has yet learned and for much which is still a closed book.

All this gives zest to our endeavor. It makes the study of man by man the most challenging problem that man can conceive. There will be many researches, many papers, many lives lived, before there can emerge that integrated, complete understanding which alone can form a sound and adequate scientific base for the profession of medicine. And in the meantime we pursue individual paths, which continually diverge, which become daily more specialized; and there is danger that the pioneers on the boundary of knowledge will completely lose touch with one another, that we shall learn

more and more about less and less, and that the grand design may be completely obscured by the inconsequential detail which we pile up before it.

I can give you no solution for the quandary in which we find ourselves. There is probably no single solution. But there are a number of things which would help.

Versatility and Understanding

For one thing, I feel that it is obvious that the present day calls for more versatility and breadth of understanding. The difficulty is to acquire these virtues without at the same time becoming superficial. I feel that in our education, not merely in the field of medicine but in all the professions, we need more emphasis on the ability to grasp, on learning to learn, with the sacrifice of a great deal of practical, detailed, factual knowledge; more dependence on ability to find and evaluate, and less on memory. For the facts presented to memory are today overwhelming in any profession, and the attempt to carry them all, even for a narrow field of practice, can lead only to mental indigestion and a stultifying of those qualities which distinguish a human brain from a book or an adding machine.

This leads to the thought that we need to give attention to the means by which our accumulated knowledge becomes stored and transmitted. The printed page, the library, the spoken word, the lecture—in the forms in which they have operated for centuries—are no longer adequate for the purpose. And we seem to be doing little to improve the means for gaining access to our accumulated knowledge, which is growing at a prodigious rate. The holdings of prominent university libraries have been doubling every 16 years for some time. The number of journals publishing results of original research runs into many thousands. The pace is now increased and especially marked in science. How many of you, for example, have time to keep up with the literature written in the various fields of medicine?

It is strange that we seem to be so baffled by this problem in these days of intense mechanization. Machinery, control devices, and instruments, have entered many a field to make it pos-

sible to contend with growing intricacy of operation. A modern bank, a modern factory or refinery could not operate without this mechanization. Sorting machines, automatic controls, applied power, and machines which make machines have enabled us to build our civilization to its present point of high individual productivity, interrelationship, and standard of living. But these things have hardly touched as yet the ways in which we store and communicate our findings and our thoughts.

New Methods of Publishing

Books and journals published for a limited group such as yours are bound to be expensive; they cannot be produced by conventional means at prices that are easy to bear. This fact tends to reduce further the size of the group that can have easy access to them, however essential to your profession may be the information they contain. True, there are devices being built which will greatly decrease the cost of printing on paper. The day of metal type, which has served so long, may be nearing an end. New electronic photocomposition machines are beginning to produce books, and this is by no means the final step in a revolution of methods of printing.

We also have microfilm. With some of the refined types of film developed during the war it is no exaggeration to state that the *Encyclopaedia Britannica* could be compressed to the size of a matchbox. There are all sorts of useful but not revolutionary card sorting processes and the cards can carry microfilm. There is a little used machine in existence—the rapid selector—which can review items on a strip of microfilm at the rate of 1,000 items a second and print those which are selected in accordance with a code set on a keyboard. It could, for example, review the case histories of half a million hospital patients in 10 minutes and present for aid in diagnosis printed copies of the few cases which corresponded to an unusual set of symptoms and complications. I say it could, but as yet it does not.

We might profitably give some attention to our methods of indexing and cataloging scientific literature. In an era of chemical physicists, physical chemists, biophysicists,

biochemists, neurologists, neuropathologists, neurosurgeons, clinical psychiatrists, and so on, it is difficult to know how our knowledge ought to be classified and how to thread our way through the classifications, once they are temporarily established, to find the information that we need.

The rapid selector mentioned above will select according to an established code, but the code must be developed on a rational principle so that it can be effectively operated. No system of coding or of indexing under established subject heads can efficiently serve to guide us through the written thoughts or findings of scientists when the very science in which they work will not submit to definition. We can only wish—the optimists among us may hope—that a way will be found for converting into some form of mechanism the kind of fluid indexing and cataloging that takes place in our minds. There is here a feature which man has not yet introduced into his machinery, a feature of great power, the pursuit of paths through a complex record by means of association of ideas. Modern electronics can do for us almost anything we ask in the way of rapid, involved operations upon masses of data. But we still tell our research findings to one another in much the same old way, and we record our research results in a mass of paper from which their extraction becomes increasingly laborious.

Two Lines of Practical Action

There are two very concrete things that we can do in the present situation that can help enormously.

In the first place, we can be intelligible. We can school ourselves—all of us—to express ourselves so that what we have to communicate can be quickly and easily apprehended by others within our profession and in the nearly related professions. There is, as has recently been said, a moral obligation upon all of us to be intelligible.

In the second place, we can gather, integrate, interpret. We can take measures to encourage a few at least within our professions who have the native skill to gather, summarize, and interpret the information developed by many workers—who can make great masses of seem-

ingly confused data clear, intelligible, and useful to their fellows. Men possessing this kind of skill are rare and need to be encouraged. In these hurried days their efforts in explaining where we are, where we are going, and what recent developments really mean, is utterly invaluable.

I said before that the most helpful thing that can be done to advance fundamental science is to find the truly gifted scientist and support him to the utmost. Let me repeat this for the individual who can integrate the current stream of emerging knowledge. Only too often his work does not receive the recognition it deserves, and his labors are performed at the sacrifice, not only of his own career in strictly novel research, but also of his scale of living, for the direct rewards of this sort of publication are not large. I wish there were more generous support for labor of this sort and more recognition for this type of attainment. Had I invented a new dynamite and reaped a fortune from it, I should be inclined to establish a Nobel Prize for the integrator and interpreter of science, who can in these days often serve his fellows far more

than the individual who merely adds one morsel to the growing, and often indigestible, pile of accumulated factual knowledge.

The dangers and difficulties which attend us as the pace of scientific research is quickened and the field of knowledge expands into many new paths . . . are real, and we would do well to devote deep thought to their avoidance and to finding solutions for the problems they present. Still, the most significant aspect of the present day in science is that we are going ahead energetically and accomplishing much. . . . It is far better that we should be embarrassed by the consequences of our rapid progress than that we should be bogged down to a snail's pace. Our problems of integration and interchange are solvable if we will devote enough of our energy to grappling with them. . . .

These are invigorating days in science and its applications. And if we can only avoid the disaster of another world war, I am convinced that we are on the threshold of great things, full of hope for a better future and a more healthy, happy race of men.

Five Reports on Psychosocial Aspects of Cancer

During the National Conference of Social Work sessions at Chicago in May 1952, the American Cancer Society sponsored discussions of the psychosomatic and psychosocial aspects of cancer under the general title, "Living With Cancer." *Public Health Reports* is publishing in this issue the fifth and final paper selected from these discussions—"The Aggregate Community Picture," by Edna Nicholson (see facing page 169). The four previously published papers are:

Professional attitudes and terminal care, by Charles S. Cameron, October 1952, pp. 955-959.

Typical patient and family attitudes, by Addie Thomas, October 1952, pp. 960-962.

Psychological impact of cancer surgery, by Arthur Sutherland, November 1952, pp. 1139-1143.

The sequence of emotional reactions in radical mastectomy patients, by Morton Bard, November 1952, pp. 1144-1148.

The Aggregate Community Picture

By EDNA NICHOLSON, M.S.P.H.

ATTITUDES are the source of action whether they are those of the individual or of a community of individuals. Community attitudes toward cancer are vastly important because of the ways in which they affect human suffering and what is done to relieve it.

Community-wide participation is essential if the necessary services and facilities are to be available. Effective provision of these services and facilities involves significant numbers of highly trained personnel, necessitates the spending of large sums of money, and requires good community planning and coordination.

Unless effective community provisions have been made, little can be accomplished either on a mass basis or in obtaining good diagnostic and treatment services for an individual patient. Provisions must include:

Research. Research does not consist of some form of magic. It does consist of endless hours of painstaking effort by highly trained personnel, working with specialized and often very expensive equipment in places where the necessary material is available, the facilities are adequate for their needs, and the funds are sufficient to meet the cost.

Education of professional personnel. Well-staffed, well-organized, and well-financed educational and training centers are essential if there are to be good doctors, nurses, social workers, health educators, laboratory and X-

ray technicians, and other essential personnel available when needed.

Education of the public. Not enough is known about cancer to cure all cases even though discovered early. But the number of persons dying for this reason is perhaps far less than the number who are suffering and dying because they did not seek care early, or did not present themselves to reliable physicians, or did not follow the advice they received at a point where it might have controlled the condition and saved their lives. Procrastination and quackery are making ready victims of cancer patients. Broad and effective community programs are needed to educate the public.

Hospitals and related facilities and equipment. Facilities are needed for diagnosis, for surgical care and other types of treatment, and for good care of patients, including terminal care. The size, complexity, and cost of these facilities and equipment are such that there is little or no possibility of providing them without broad community participation.

Coordination of services. To achieve the best possible care for patients and the most efficient use of community money, there must be provisions for coordinating the many specialized services which may be required for the individual patient and adequate machinery to achieve effective coordination in community planning and action. This need was sharply delineated in a recent study of terminal care for cancer patients. Intensive study of more than 5,000 cases in an urban area showed that, in general, almost enough facilities and services were available in the community to provide the necessary care, but that many patients were not receiving the care they needed because they did not know it was available, or because the patients needing

Miss Nicholson, director of the Central Service for the Chronically Ill of the Institute of Medicine, Chicago, presented this paper as a part of the American Cancer Society's program at the National Conference of Social Work held in Chicago, May 27, 1952.

the care and the resources available to provide it were not getting together. Deficiencies in community resources need to be clarified, unnecessary gaps and duplications eliminated, development of new facilities and services guided, and existing sources operated and used with effectiveness for the patients and economy in expenditure of community money.

Meeting the costs of medical care. Provisions must be adequate for persons unable to pay. At present we have far too many different public assistance programs responsible for financial help to needy people, with too much personnel and money being wasted in maintaining artificial distinctions between specialized, categorical programs. And almost all of them are operating on seriously inadequate standards in staff and services and in the assistance they are providing to needy cancer patients along with other dependent people.

Obviously, there are many factors which influence the adequacy with which any community provides the services necessary in the control of cancer and in the diagnosis, treatment, and care of persons suffering from cancer. Highly important among these factors are the attitudes with which the community regards cancer and its responsibility for meeting the problems related to it. There is nothing mysterious about community attitudes. They represent merely the aggregate of the attitudes of the individuals who make up the community. If most of the people in the community regard cancer with such fear or guilt that they cannot accept the problems calmly and plan wisely to meet them, these attitudes almost certainly will be reflected in poor community planning, disorganization, and inadequate services. If a majority of the individuals in the community are selfish and indifferent to the problems of people who are sick and in trouble, their attitudes will be evident in lack of effective community support and an inability to develop and maintain good services. Conversely, when a majority of the individuals in the community feel a sense of responsibility for their fellow men; when they are realistic and objective in facing facts; when they are moved by humane understanding and intelligent compassion, their community will have good services and the fullest advantage will be taken of all existing possibilities for the prevention

and control of cancer and for the diagnosis, treatment, and care of persons affected by it.

Fear of Cancer

One of the most prevalent and potentially damaging attitudes toward cancer is fear. The fear of an individual that cancer may strike him or that it may take away someone he loves is so widespread as to be almost universal. It may be a normal and perfectly intelligent reaction to reality. It is one of the strong factors which helps to motivate intelligent people to consult a physician and to follow his advice. It causes communities to provide the money and to take the action necessary to assure that good services and facilities are available for the management of cancer.

However, uncontrolled fear of cancer is likely to defeat the very purposes it should serve. Uncontrolled fear may be evidenced by refusal to face the facts and by consistent efforts to avoid all contacts with realities which must be faced if anything constructive is to be done about cancer. This results almost inevitably in a lack of sufficient services, inadequate support for good services, and poor planning—or no planning at all—in the development of new facilities and services.

Often fear of cancer results in such panic that there are intense demands for community action, but the demands are accompanied by such strong emotions as to make sound, realistic planning impossible. New facilities then may be developed blindly only to discover too late that they are not of the type suitable to meet the real need. Uncontrolled fear may be expressed in the form of a paralyzing hopelessness which makes it difficult or impossible to develop and maintain good community services.

Association of Guilt

Feelings of personal guilt are widely prevalent in the care of cancer patients. Usually, they arise from situations in which relatives become deeply disturbed by some failure, or imagined failure, in their past relationships with the patient. As they face the more or less imminent possibility of the patient's death they may be almost overwhelmed by their feelings.

and may begin to reach out frantically for ways in which they can compensate for their failures and reassure themselves regarding their devotion to the patient and their general worth as human beings. These feelings probably are much more widespread than is generally recognized. Like fear, guilt may be so common as to be part of a normal reaction.

Some release for the feelings is essential. In many instances, of course, the individual is able to adjust to the situation with reasonable success. In others, however, he may be so driven by his feelings that he becomes excessively protective of the patient, oversentimental about all cancer patients, critical of the doctors, nurses, hospitals, and others in the community, and a source of disturbance in efforts to meet community problems. He may find others who share his emotional distress and his feelings of rebellion. Another "crusading" group in the community may be the result, guided by emotion rather than facts and acting on impulse without sound guidance—and sometimes in rebellion against sound guidance. Groups of this kind tend to spring up everywhere. Usually, they do not reach sufficient size nor have sufficient stability to achieve substantial results of any kind. They may endanger good community services, however, by diverting badly needed interest and support from those which have value to those which do not.

Bane of Self-Interest

It is an entirely normal reaction for each individual to consider, first, his own comfort and security. It is not surprising, therefore, that self-interest is found in community services for the management of cancer just as it occurs elsewhere in human life. There are varying degrees, however, in the attitudes of individuals and communities toward their fellow men. In some the prevailing attitude seems to be one of indifference—or even of censure—for people in trouble. Where little, if any, feeling of community responsibility for people who are hopelessly sick and dependent exists, it is difficult or impossible to develop and maintain good community services.

In other places, the situation seems to be only slightly better. These communities may not

be able to ignore their responsibilities completely. They may enact laws making legal provisions for the care of sick or helpless people, but, because they are not willing to make real sacrifices of their own comfort and security, they may give so little financial and other support to the programs that the laws have little effect.

In some communities, various civic and professional groups may deplore the absence of good community services but be unwilling to submerge their own vested interests sufficiently to achieve effective, well-rounded community action. Social workers criticize physicians for not supporting a plan which the social agencies develop. Hospitals and doctors criticize the social agencies. Businessmen and labor leaders are critical of all of them. And while each is blaming someone else because the community does not have the facilities it needs, no one is submerging his own particular interests and point of view long enough to make an honest effort to understand the problems of the others; and the people who desperately need care continue to be left without it.

There is another aspect of self-interest which also may endanger good community services for cancer patients. Often it is a subconscious type of self-interest buried under an apparently sincere and zealous devotion to the development of good health and welfare services in the community. There are persons and organizations who sponsor a "cause" in an effort to gain social prestige. There are others who are hungry for personal glory and power and are willing to work hard for good community services only so long as they can dominate them and receive widespread credit and publicity for their good deeds. These people and groups in the community often are motivated by self-interest of this kind without fully recognizing it. They may believe themselves to be concerned sincerely for the welfare of the people they supposedly are serving.

Constructive Attitudes Toward Cancer

Fortunately, in every community there are attitudes which have constructive effects upon the development and maintenance of good community services. In all communities these

attitudes are present to some extent. Even in those places where they seem to be overshadowed by less wholesome attitudes, it is probable that they can be found in some degree and, with care, can be increased to a point where eventually they predominate in controlling community action.

In any effective effort to assure good facilities and services to meet the problems presented by cancer, it is important that such attitudes characterize the planning and action of the community.

A sincere sense of responsibility for helping people who are sick and in trouble implies more than a sentimental desire to relieve suffering. It includes a broad responsibility for assuring that real, practical help of good quality and adequate amount actually is provided and kept consistently available.

A realistic acceptance of the importance of factual information with careful analysis of problems, sound planning, and consistent long-range effort is essential. The problems which now stand in the way of good community facilities and services for cancer patients have been growing for many years. They are deeply rooted and are intertwined with many other health and welfare problems in the community. If they are to be solved, there must be accurate information about what the problems really are; how much is being done to meet them; what specific factors are operating to cause the existing deficiencies; how these factors can be overcome; specifically what new facilities and services are needed and how many; where they should be located; how they should be operated; what their relationship should be to other essential community services; and how these facilities and services can be financed. These patients have waited too long, and their needs are too desperate, for us to fail them now by not accepting the need for clear thinking and long, hard work.

There are many individuals and many communities who would like to have better facilities and services available for cancer patients. Too often, however, their desire for these services is spasmodic and does not go deep enough to accept and meet the necessity for assembling and analyzing factual information to clarify the needs, for formulating effective plans for

meeting them, and for working consistently over long periods of time to assure that the needs are met. Instead, they tend to seize upon whatever idea presents itself on the spur of the moment and to base their actions upon superficial thinking and too few facts.

It is under circumstances such as these that communities fail to distinguish clearly between a need for more beds for cancer patients and a need for more adequate funds to pay for care of patients in beds which are available. This type of approach may lead to the development of specialized hospitals and related institutional facilities exclusively for the care of cancer patients, when closer integration of cancer facilities with general hospitals and medical centers might provide better services and entail less cost to the community. The same approach may be responsible for the "pesthouse" type of planning which establishes separate institutions exclusively for terminal care of cancer patients. All of these things may be done with the best possible intentions. Certainly, good intentions are greatly needed. They must be supplemented, however, with a realistic understanding of the need for facts and clear thinking.

Understanding and acceptance of the emotional aspects of human behavior and the emotional requirements of the individual is another community goal. We have tried too often to choose between intelligence and emotion on the assumption that these two qualities necessarily are antagonistic. Yet, the human being is an indivisible combination of both qualities, and there is no way in which human needs can be met adequately without consideration for both.

For humane reasons, the emotional effects of various types of facilities and services must be fully considered. Because of the strong influence of emotions on human behavior and on the ways in which community services are used by people in need of care, it is essential also for very practical reasons. It is unrealistic to attempt to plan community services without consideration of the probable emotional reactions of the patients, their families, and the community to the various types of services under consideration. Similarly, intelligence must be used if there is to be any hope that the services will be stable, well-operated, and effective.

Statistics in a Health Department

Medical Care Plan

By MATTHEW TABACK, A.M., and HUNTINGTON WILLIAMS, M.D.

THE FUNCTION of statistics in the sense of analysis of collected data and the methodology for data collection will be discussed in this paper in relation to three phases of medical care administration: (a) formulation of the initial medical care plan and its close guidance during early operation and subsequent development; (b) determination of patterns of utilization of services, including statistics on failure to use, as well as injudicious use of medical care benefits; and (c) determination of quality of medical care. Medical care statistics as indexes for planning and administration have been stressed elsewhere (1).

Health Departments and Medical Care

Due to the success of health departments and medical research in communicable disease control and as a result of the recent marked declines in infant and tuberculosis mortality, prevention and control of disease among the indigent through provision of early and comprehensive medical care has become increasingly a responsibility of the local health department. Consistent with this trend, the Association of State and Territorial Health Officers in 1950 officially requested that administration of public medical care programs be placed under the official health

agency (2). Thus by 1950, Terris and Kramer (3) report, "62 or 5 percent of all full-time health departments have responsibilities for administering general medical services of varied scope and character."

The medical services most commonly provided are those of the physician in the home, clinic, or office and the provision of drugs and laboratory services. The geographic coverage of these health department administered programs varies from Maryland's state-wide plan for relief clients and medically indigent persons to programs covering small counties and cities of approximately 25,000 population.

The medical care programs in Maryland represent the result of intensive investigations by the Committee on Medical Care of the State Planning Commission during the period 1940-46. Following separate studies of the medical needs and resources of the counties of Maryland and of Baltimore City, two distinct and administratively independent programs were established. Both county and city programs are concerned with indigent persons and are founded upon the concept of family coverage for specified periods of time.

Baltimore City Program

The persons covered by the Baltimore City medical care program initiated in 1948 are referred by the welfare department to the health department. Assignment for medical services, regardless of any stated need, is made by the health department to an appropriate medical care clinic. Cooperating with each of the six medical care clinics is a panel of physicians, one

Mr. Taback is director of the bureau of biostatistics and Dr. Williams is commissioner of health, Baltimore City Health Department. This paper was presented June 20, 1952, at the Second Conference on Public Health Statistics, School of Public Health of the University of Michigan, Ann Arbor (see Public Health Reports, August 1952, p. 725).

of whom is selected by a representative of the family. The family has free choice of physician and the physician retains the right to refuse to accept as patients any family. The manner in which services are rendered is shown in table 1.

Two points should be emphasized. The population covered is always known both in numbers and in detailed characteristics. The health department is primarily responsible for integrating the program; it has very little responsibility for providing services directly.

In view of the initial size of the program (population to be covered estimated at 21,000), it was decided to establish in the medical care section a statistical unit responsible for advising the medical care program. This unit receives technical assistance from the bureau of biostatistics and concerns itself with the accumulation of data required for evaluation and program analysis as well as with maintenance of the records system for disbursement of funds.

Benefits to patients and cost per service are two basic concepts fundamental to any assessment of a medical care plan. The success of such a plan can be measured by the extent to which it meets the essential medical needs of the population to be covered and by the amount and quality of services rendered per specified unit of money expended. Several procedures which

assist in the guidance of a program providing maximum patient benefit at minimum cost are described.

Indexes for Planning

A medical care program must be tailored to fit the population to be covered. In figure 1, the population of the United States, by age, is contrasted with the group covered by the Baltimore City medical care program and the enrolled members of the Health Insurance Plan of Greater New York (4). The indigent population of Baltimore has an extremely high proportion of persons at each end of the age scale, with a resultant low level in the middle-age categories. Compared with the general population, Baltimore has few persons in the young and middle-adult period. Note the opposite pattern in the age profile for the Health Insurance Plan, in which the adult ages predominate and persons in the older ages are few in contrast to the general population.

An examination of the age characteristics of the group covered by the Baltimore City medical care plan shows that the needs of a public assistance group are particularly associated with the problems of the aged, and in addition should provide an extensive preventive and pediatric service for the large numbers of children found in this group.

Analysis of the race and sex characteristics of the public assistance population (table 2) reveals a markedly different distribution than that of the community. Table 3 shows a definite excess of Negroes in the medical care group at most age levels, and significant concentration of females for the adult ages, suggesting a pattern of medical need associated with conditions commonly found among Negroes and among women.

A knowledge of the environmental and socioeconomic circumstances of the population to be covered by a medical care program furnishes useful information on the capabilities of the beneficiaries to assume responsibility for the care of ill members in the home or to benefit from health education efforts.

Figure 2 indicates the geographic characteristics of the covered population. White persons appear to be widely distributed throughout the city, with a small number of concentrated

Table 1. Agencies providing medical services and method of payment, Baltimore City medical care program

Agency	Services provided	Method of payment
Private physician.	General care in the office or home; day and night.	Capitation: \$7 per person referred per year.
Medical care clinic.	General examination, diagnostic and special therapeutic services.	Capitation: \$10 per person referred per year.
Neighborhood druggist, hospital pharmacy.	Preparation of prescriptions as written by participating physicians.	Fee for service: based on wholesale cost of ingredients plus service fee.
Health department.	Clinical services: well-baby, prenatal, tuberculosis, venereal disease.	Free.

PERCENT OF POPULATION PER YEAR OF AGE

Figure 1. Distribution of selected populations, by age.

foci; the nonwhite medical care group is densely concentrated in the hub of the city.

Detailed housing statistics by census tract reveal the slum conditions in which the Negro group resides. Data on density of households indicate extreme crowding. With a few exceptions, the environmental circumstances of a considerable proportion of white covered families are more favorable than those of the Negro family units.

The limitation which the medical staff must expect in capabilities of patients for modification of the location or nutrition of the family is clearly demonstrated by the family budget. In 1950, according to an estimate of the Bureau of Labor Statistics (5), an elderly couple required an annual income of \$1,779 to maintain a modest standard of living. For elderly couples in the medical care program, who are dependent on welfare department grants, the current average income per couple from all sources is \$1,134, considerably less than that considered sufficient.

Estimation of Medical Needs

In developing the detailed organizational framework for administration of a service program, some estimate is necessary of the utilization

expected within a given pattern of providing care. Especially is this true for programs predicated largely on a capitation principle. Underestimates of utilization may cause hardship and dissatisfaction among the participating physicians. Excessive overestimate will result in a distribution of public funds which cannot be defended in budget reviews.

Several lines of attack on this problem were available at the initiation of the Baltimore City medical care program. The experience since 1948 both in health department programs and in such units as the Health Insurance Plan of Greater New York provides more recent information for planning purposes.

In considering an indigent urban population, it is well to recall that a principal source of medical service is the hospital out-patient department. A check of services to indigents during a prescribed period of time, when related to the known population of such persons, provides an estimate of utilization of clinical services as well as of their distribution by type.

Although 20 years old, the findings of the Committee on the Costs of Medical Care have great potential value as first approximations of expected volume of medical services in a com-

Table 2. Percentage distribution of population by race and sex, total Baltimore City and persons covered by Baltimore City medical care program

prehensive program. In one of the committee's investigations, Falk, Klem, and Sinai (6) present information on services received during a 12-month period, according to family income. Utilization of the higher-income groups in this study represents a reasonable basis for expected utilization in a health department sponsored program. Baltimore has been fortunate in serving as an area for a 5-year study of causes of illness and utilization of medical services conducted during the period 1938-42 (7, 8). This type of investigation provides data of inestimable value and accuracy. Care must be taken in applying such material to populations with unusual distributions in respect to age and race; but with appropriate correction, observations made from such surveys furnish another

source of information upon which an estimate of utilization may be based.

Survey of Medical Resources

In formulating the initial medical care plan, it is necessary to determine whether the medical facilities are sufficient in number and properly disposed to meet the objectives of the program.

The blueprint for the Baltimore City medical care program places in the hands of the general practitioner the means to provide basic medical care for all covered families. One of the first tasks, therefore, was to determine the distribution of physicians in general practice with respect to location and number.

(table 4), as well as the geographic distribution of white practitioners, suggested no particular problem. The prevailing pattern of home and office care is such that white physicians provide care to white families and Negro physicians provide ambulant services to nonwhite families. A large proportion of indigent families received the equivalent of home and office care in the hospital out-patient departments prior to the establishment of the Baltimore City medical care program.

The story was vastly different for the non-white group. Not only was there an unfavorable ratio of physicians to population served, but the geographic distribution suggested that great difficulty would be experienced in finding personal Negro physicians for the families to be covered by the program. As a result of this analysis, attempts were made to attract new physicians into areas where a large-scale need existed.

Similar studies established the adequacy of clinical facilities in general hospitals and of neighborhood pharmacies, so that no unusual problems ensued in obtaining services of these agencies.

Indexes for Program Control

Progressive medical care administration must be based on a thorough understanding of the specific disease entities which a group presents. Information available from selected studies of out-patient records, morbidity studies, and discussions with physicians familiar with a given population segment provides a working basis for initial planning. However, as soon as possible, accurate and complete data on the conditions presented by a covered population should be obtained.

The Baltimore City medical care program provides for a general examination by one of the medical care clinics for every person referred to it. The results of this thorough medical survey yield invaluable statistics concerning the amount, classification, and severity of medical problems presented by an indigent population. A summary of this type of data is shown in table 5. However, some qualification is necessary. The persons included in this summary represent an unbiased sample of adults who have completed examinations at one of the participating medical care clinics. Although

Population per physician----	842	701	2, 675

all persons registered at the clinic are scheduled for examination, approximately 12 percent fail to avail themselves of this privilege. In presenting the information available from the clinic histories selected, use has been made of the Sixth Revision of the International Lists of Diseases and Causes of Death, adopted in 1948, and a modification of the classification recommended for morbidity purposes has been employed.

The data in table 5 reveal a striking amount of disease diagnosed. (The high place of venereal diseases and diseases of the female genital organs would seem most unusual were it not consistent with early conclusions, drawn on the basis of population analysis.) However, the health administrator needs more information than the diagnosis alone provides. To assist

him in interpreting the data, the examining physician should supply, in addition to his diagnosis, information as to what limitation the patient's condition will impose upon his daily capabilities to perform useful work.

When the data in table 5 are further classified as to whether the diseases are disabling or not, they may serve as a basis for estimating requirements for specialists' and laboratory services. Any program for postgraduate instruction should seek to assist cooperating physicians in effective management of the more prevalent disabling conditions.

The study of clinical histories of the individuals included in this investigation showed that 850 or 87 percent of the persons examined had previous hospital or out-patient records, many of which were extensive in detail. Such records are believed to be characteristic of urban indigent groups and suggest that there should be some compromise with the concept of a complete physical examination for each individual in a medical care program.

Patterns of Utilization

In developing capitation fees, utilization rates were estimated from national as well as local surveys. In view of the unique distribution of care in the Baltimore City medical care

Table 5. Principal disease groups observed in general examinations of 975 indigent persons, aged 15-64 years, Johns Hopkins Medical Care Clinic, 1950¹

Disease groups ² (listed in order of total prevalence)	Total prevalence		Previously diagnosed		Newly diagnosed

program, it has been necessary periodically to assess the extent to which facilities have been used by the covered population. In achieving this objective, it has been a standard procedure to develop suitable statistics from records which are essential for medical management or from an administrative point of view. Thus, clinic and drug utilization are determined by a study of the clinical histories and drug invoices for a systematic stratified sample of the covered population. Physician utilization studies are dependent upon the accuracy with which physicians check on a quarterly patient roster the number of visits made and have been somewhat difficult to accomplish because of the incompleteness of data provided. Nevertheless, the rough approximations which have been possible are administratively very worth while.

From the 1949-50 experience, utilization rates of benefits offered under the Baltimore City medical care program are shown in table 6.

By determining the amount of money which would be required to provide the services performed by the general practitioner if a fee for service were paid, it is possible to evaluate the correctness of the capitation fee. A similar mode of study is possible in regard to the clinic role in the program.

Age specific rates of utilization of services are often of great value in pointing out which segments of a covered population are the most costly elements. They assist also in planning extensions of the program to additional groups. An example of this type of data is shown in table 7.

Several other descriptions of utilization of services are worthy of mention, such as distribu-

tion of persons by length of membership in the program and by number of services received.

Recent analysis of length of stay on the program indicates a 25-percent reduction in need for clinical services during the second year of registration, indicating in part the advisability of developing a stable program of care for any population group.

On occasion, a distribution of individuals according to number of services received has been most illuminating. Using such a classification, it may prove possible to encourage a thorough review of a small number of persons who are receiving a markedly disproportionate share of total services provided in a given time period.

Failure to Use Services

In assessing the manner of utilizing program benefits a group which fails to respond by initial registration or to appear for general examination constitutes a problem which requires study. The administrator is not trying to create unnecessary activity. Rather he desires to introduce the concept of early care and prevention to a group of families who may not appreciate the value of preventive measures.

During the early operation of the Baltimore City medical care program, it was found that approximately 40 percent of the families failed to respond to notification to register at one of the medical care clinics. Analysis of the age, sex, and race characteristics of this group did

not indicate any striking difference from the equivalent statistics for the total of persons assigned. It was decided, therefore, to conduct a systematic inquiry of the response pattern of a block of families assigned to one of the clinics. The results of this investigation are shown in table 8.

As a result of this investigation, and after a careful study of the reasons for nonresponse noted by public health nurses, who were used on a trial study basis, a successful pattern of contacting families has been evolved, eliminating the nonregistrant group as a significant segment of the medical care population.

Variability in Utilization Patterns

In any medical care program, a range of patterns will develop, in addition to some average tendency. One of the most useful techniques in the application of statistics to operation analysis is the description of variability in utilization patterns in a manner which permits a value judgment and leads to an administrative decision.

Some of the practices which have been critically analyzed and which should be of interest to any administrator are:

1. Prescription-per-visit ratio according to physician.
2. Physician referrals for consultation per 100 person-years' coverage.
3. Percentage distribution of prescriptions classified proprietary or nonproprietary.

Table 8. Registration pattern of a block of assigned persons, according to notification procedure, Sinai Medical Care Clinic, 1949

Notification procedure	Total persons notified	Number registered	Registration per 100 persons notified	Cumulative percent registered
Introductory card including appointment	879	537	61.1	61.1
Follow-up form letter including appointment	468	153	32.7	78.5
Nurse's visit	106	76	71.7	87.2

Determination of Tolerance Limits

If C = Total annual prescription cost

c = Cost of a single prescription

N = Total annual number of prescriptions

n = Annual number of prescriptions filled in a single pharmacy

Then $\mu = C/N$ and $\sigma = \sqrt{\frac{\sum c^2}{N} - \mu^2}$

and $\mu \pm 3\sigma/\sqrt{n}$ = Limits within which the mean prescription cost of an individual pharmacy with an experience of size n may be expected to vary by chance from the mean, based on the total experience.

4. Error rate in billing, according to pharmacist.

5. Mean cost of prescriptions, according to pharmacist.

No doubt there will be other indexes which will warrant study, depending upon the organization of the program for providing services. It is beyond the scope of this paper to demonstrate the techniques of using each of these indexes to point out patterns of possible injudicious use of the program's benefits. It will be of interest, however, to show how the analyses of data on two of these items contribute to reductions in the cost of administration.

Because the cost of drug service constitutes approximately 25 percent of total expenditures in the Baltimore medical care program, and because it was suggested that use of nonproprietary preparations whenever possible could result in significant savings, an analysis was undertaken of a systematic sample of prescriptions processed in the fiscal year 1951.

The proportion in each drug classification which proprietary drugs bear to the total varied within wide limits, representing over all 55.4 percent of the total prescription experience. The proprietary drugs were then submitted to a physician-pharmacist team who, with the guidance of a statistician, classified the prescriptions with reference to an official alternative and indicated the approximate saving in

cost. The results of this evaluation are shown in table 9 and indicate that \$16.30 per 100 proprietary drug prescriptions would have been saved if complete use had been made of the United States Pharmacopeia (10) preparations. When considered in terms of the total drug experience, this saving is equivalent to a 6-percent reduction, or \$9,000, for the volume encountered in the fiscal year 1951, during which the drug bill of the Baltimore City medical care program was \$150,000.

Procedures Useful in Cost Control

Basic medical and drug services are provided by some 300 physicians and 500 pharmacists cooperating with the Baltimore City medical care program. The mean number of patient visits per 100 persons on a physician's list will vary with each physician. Reports by druggists will vary, among other things, in the average cost of prescriptions filled in their establishments.

To discover differences in practices of pharmacies within the drug program, variations in mean cost per prescription were studied, using the procedure shown in the accompanying box.

Pharmacies filling 100 or more prescriptions annually were regarded as unbiased samples of the total annual prescription experience having known mean and variance. Individual pharmacy differences from the total mean were evaluated in terms of the tolerance limits established.

A detailed study was made of invoices submitted by pharmacies with mean prescription costs lying outside of expected limits. In a few cases, the differences appeared to stem from an unusual character of the sample. In some instances, however, this technique proves useful in uncovering consistent deviations from standard cost practices. Such deviations can be obtained in either direction and are of equal interest so far as cost analysis is concerned.

Determination of Quality of Medical Care

In assessing the quality of a medical care program, it is necessary first to seek a definition of the characteristic to be measured. A definition which provides for no possible method by which the attribute "quality" can be quantitatively fixed will lead into a blind alley. How-

ever, in developing this new scale, broad measurement intervals will suffice until experience permits a finer scale. Necessary conditions are:

1. A standard based on total patient benefit.
2. Until such a standard is developed, a criterion based on program components. This criterion should include measurable attributes, such as performance of physicians, accuracy and completeness of medical care records, and accuracy of laboratory determinations.
3. The availability of resources is a limiting factor in performance and should be considered when interpreting quality measurement.

One attempt has been made to establish criteria which would allow for an evaluation of therapy employed in the Baltimore City medical care program insofar as data on drug prescriptions can provide information on this subject. By conference with an expert committee, a classification was devised which distributes prescriptions according to their therapeutic advisability. The principal considerations involved in establishing the classification were: (a) therapeutic, chemical, and pharmaceutical compatibility of ingredients; (b) rationale of treatment, considering the condition involved and the patient's age; and (c) availability of more effective drugs.

The results of this study are in process of analysis and will be reported later.

Conclusions

Statistical methods represent an efficient way to gather information and to make it useful for administrative decision.

The particular contribution of the statistician to problems of administrative analyses as these analyses concern determination of quality lies in the development of well-defined classifications of performance with previously assigned values.

Built into the program from the start was a statistical study unit. The work is going forward for approximately 3 percent of the city's population who receive public assistance, with continued attention given to the guidance that may be derived from statistical analyses. The administration considers such "chart and compass" facilities to be indispensable.

Selective Case Finding in Syphilis Control

By GEORGE MOORE, M.D., M.P.H., and MALCOLM T. FOSTER, M.D., M.P.H.

IN VIEW of the gradual decline in the number of cases of syphilis reported by State health departments year by year, most public health authorities have been aware of the need for radar-like methods to pinpoint undiscovered syphilitics in the population. Evan Thomas (1) has suggested that when the prevalence rate of syphilis is low, blood-test screening of total populations is not entirely feasible. As the incidence of syphilis in the population decreases, the cost of finding a case by mass blood-testing increases proportionately. In recent years, mass blood-testing campaigns have been waged in many of our major cities, such as Charleston, S. C. (2), Philadelphia, Pa. (3), Atlanta, Ga. (4), Detroit, Mich., and New York City. Because of variable results and high initial costs, the more recent surveys have emphasized screening of high-prevalence groups or areas rather than entire populations. The selective approach has proved its merit; nevertheless, the campaigns have required considerable personnel, effort, and money. They have also proved to be short-range procedures, as the populations tested are usually prone to reinfection.

Several States, notably Mississippi and North Carolina, have recently become interested in long-range, selective, group-screening methods. In Mississippi (5), the State Board of Health has considered placing emphasis on the population for survey rather than on the individual. They point to surveys as an effective method of

finding cases of late and congenital syphilis at low cost. Better education is also listed as an advantage.

In North Carolina, the State Board of Health has organized a venereal disease survey team consisting of six to eight trained Public Health Service investigators. At the request of a county health department, this team arranges and conducts blood-test surveys of select-group populations. Drs. Wright and Sheps (6), of Chapel Hill, N. C., discussing screening methods, suggest that the major value of such surveys is to reduce the backlog of old cases and to prevent congenital syphilis.

Interest is being shown in the sociomedical aspects of venereal disease more than ever before, and it is natural that this interest should enter the realm of screening methods. For example, H. Garriek Williams (7) describes his experiences with blood testing in pool halls and taverns, where 12.8 percent of the persons tested were reactors. W. Lloyd Warner and associates (8) have studied syphilis prevalence and community structure, using as their material a blood-testing campaign in a Georgia town. They found 0.6 percent white and 13.6 percent Negro reactors, and determined that groups with a lower social status contributed the highest percentage of positives. The authors write, "It is important that groups of the population with higher prevalence and incidence rates be identified so that activities can be directed toward them. . . ." Other authors have pointed out the effect of socioeconomic factors and marital status on syphilis prevalence (9, 10).

This paper describes briefly three methods of screening employed by the Cumberland County Health Department during the past year. These

Dr. Moore and Dr. Foster are with the Cumberland County Health Department, Fayetteville, N. C. Dr. Moore, of the U. S. Public Health Service, is venereal disease control officer and Dr. Foster is the county health officer.

methods suggest long-range blood-test surveys, aimed at high-incidence groups, that can be adapted to most local health departments because of the limited cost and unnecessary "extras."

Diversified Industrial Surveys

From October 19, 1951, to June 15, 1952, the venereal disease division of the Cumberland County Health Department, consisting of two investigators, one clerk and the venereal disease control officer, visited 36 small industrial plants and, at semiweekly intervals, the county jail. The plants were selected for their unskilled and semiskilled employees, regardless of race, and included laundries, fertilizer plants, construction groups, city sanitation units, feed mills, coal and fuel companies, lumberyards, foundries, cement works, and brickworks, as well as the 654 county jail prisoners.

Plants employing over 50 men were not included in the survey, as arrangements had been made for the State venereal disease survey team to visit the county later. The time required for the surveys averaged about 1 hour a week for each of the four members of the venereal disease division. Thus, the survey fitted into the usual routine of venereal disease control work and caused no interruption of regular activity of the division. In fact, a diversified activity was begun which proved to be highly profitable.

A total of 1,483 persons was tested serologically in the 8-month period. Negroes comprised 57 percent of the group (the percentage of Negroes in Cumberland County is approximately 26 percent); 82 percent were males. By age, 54 percent were 15-30 years of age and 46 percent were 31 years and older. Table 1 illustrates the results of the survey.

Of the 244 positive or doubtful reactors, 221 or 91 percent have been brought to diagnosis. Eighty-six or 39 percent were found to need treatment. Twenty-six had late latent syphilis; 8 tertiary syphilis; 1 was a congenital syphilitic; and 51 were treated for early latent syphilis. It was significant that although 54 percent of the total group tested was comprised of youths between 15 and 30 years of age, the percentage of those in the same age range who

were found to need treatment was only 18 percent. Of the treated syphilitics, 82 percent were 31 years and older.

Eleven-Day Industrial Survey

From June 17 through June 28, 1952, the State venereal disease survey team invited by the Cumberland County Health Department completed a survey of the larger industrial plants (over 50 employees) in the county. All arrangements for the survey, including publicity, scheduling of plants, and conferences, had been made before the team's arrival. Schedules were presented at a short meeting with the team on June 16, and the survey began the next morning.

During the 11-day period, 2,360 serology tests were taken covering 37 industrial plants and special groups. The plants were of the same general description as listed for the first survey but also included textile mills, large manufacturing plants, and migrant fruit pickers. The composition of the group tested and the number of serologic tests for syphilis (STS) taken are shown in the accompanying tabulation.

<i>Survey group:</i>	<i>STS taken</i>
Industrial surveys.....	2,029
Migrant labor.....	49
Street surveys.....	205
Movies 3).....	77
Total	2,360

¹ 68 tests hemolyzed, or quantity not sufficient, or broken in shipment.

The group was weighted in favor of males (77 percent) and whites (56 percent). Forty-five percent of the group were 15 to 30 years old; 37 percent, 31 to 35; and 18 percent, 46 to 70. Results of the survey are shown in table 2.

By age, the group that demonstrated the highest percentage of positives for the Negro race was 31-45 (35 percent); the highest group for the white race was aged 46-70 (5 percent). The 15-30 age groups of both whites and Negroes proved to be the least infected groups. By sex, more Negro males in the 46-70 age group were infected (33 percent) than Negro females in the same age range (17 percent), showing that infected Negro females were younger than infected Negro males. Of 152

reactors that have already been brought to disposition, 88 or 58 percent have required treatment for syphilis; 3 percent were biological false positive reactions. The 88 diagnosed as active syphilis were distributed as follows:

Stage of syphilis:	Number	Percent
Early latent, not previously treated	16	18
Early latent, reinfection or relapse	10	11
Late latent, not previously treated	15	17
Late latent, reinfection or relapse	37	42
Congenital syphilis	1	1
Tertiary syphilis	9	10

Since "outside" personnel had been invited into the county for this survey, an estimate of survey expenses was computed. Total expense for the survey team borne by the State Board of Health was \$892.00, and for the Cumberland County Health Department, \$55.00. The cost per blood test was 40 cents and per positive serology test, \$3.73.

This survey, then, has been inexpensive in view of the high percentage of reactors found. Furthermore, as a result of the survey, familial contacts of the reactors will be found and brought to the clinic and more cases will be diagnosed and treated. The differences in percentages of positives and doubtfuls between the two surveys is probably explained by the fact that surveys of large industrial plants cannot be as selective as those of smaller plants. Differences are significant only in Negro females.

Table 1. Positive and doubtful reactors in diversified survey

Health Certification

From July 1, 1951, to June 30, 1952, data on health certificate examinations were compiled in an effort to determine the value of screening for syphilis the group required to have health certificates.

The Cumberland County Health Department's code on health certification follows closely the State rules and regulations in requiring that employees of restaurants, cafes, grills, taverns, hotels, tourist camps, trailer camps, abattoirs, meat markets, frozen-food lockers, poultry establishments, and food-processing plants be examined for infectious diseases before they are employed. The city ordinance also requires taxi drivers to be examined. State laws include examination of teachers, premarital applicants, prenatal-care patients, barbers, beauticians, cosmetologists, and welfare applicants (for training schools and boarding homes, and for placement). Certain colleges and institutions require health examinations for entrance; and domestics in private employ are required by State law to obtain a "health card."

The enforcement of the statutory laws regarding health certification is left to the health

department in all cases except the following: beverage plants and bakeries (department of agriculture); ice cream and dairy plants (both department of agriculture and health department); taxi drivers (police); teachers, barbers, and beauticians (State). Health cards must be renewed each year and may be obtained from either the health department or private physicians.

Although examination at the health department includes chest fluoroscopy and serologic test, many applicants request a blood test only from the health department and then visit their private physicians for completion of the examination.

A check on laboratory reports for the fiscal year revealed that over 5,250 residents of Cumberland County (96,000 population) requested a serologic examination at the health department for either health certification or compliance with the prenatal law; 5,190 examinees professed to have had a negative history for syphilis and were tabulated as a single group. Others who had previous records of venereal disease or who admitted previous infection were referred to the venereal disease clinic for their health cards. The laboratory data on the 5,190 health examinees who had not been reactors or syphilitics at any previous examination are shown in table 3, by race and reason for examination.

A percentage of 4.6 positives and doubtfuls for the group was considered somewhat high since nearly all the examinees professed to have had previous negative serologic tests (10 percent of the donors in the 11-day survey had had syphilis). Moreover, the group was 46 percent white and included many children, skilled workers, and professionals.

Analysis of the returned health certificate application forms, of which there were 3,703 for the fiscal year, including former venereal disease patients, disclosed a positive or doubtful reaction in 262, or a percentage of 7.1. One third of these 262 reactors were treated for active syphilis in various stages:

<i>Stage of syphilis:</i>	<i>Percent</i>
Late latent, not previously treated-----	27
Early latent, reinfection or relapse-----	42
Late latent, not previously treated-----	2
Late latent, inadequate treatment or reinfection-----	19
Tertiary-----	19

It is interesting to note that the largest single group of examinees (1,007) was the unemployed. This group was characterized by a high percentage of young females (86 percent) and of positive serologic tests (11 percent). In fact, there were more unemployed girls (870) who applied for health cards than there were girls who had jobs (751) in cafes, restaurants, taverns, or bars, and who worked as

Table 3. Laboratory data on serologic tests of health examinees, fiscal year 1952

Type of examination	White				Negro				Total

Total, exclusive of prenatal-care examinees-----	2,298	-----	-----	-----	2,029	-----	-----	-----	4,327	83.4	162	3.7

Table 4. Effect of marital instability

Marital Status	Nonreactors (percent)	Reactors (percent)
Single-----	21	13.3
Married-----	66	63.9
Separated, widowed, divorced, second marriage-----	13	22.8

maids, domestics, and cooks. Theoretically, a health card is held by the employer as long as his employee works for him, but an unemployed girl may keep her card until she is employed. The existence of a large military reservation in the county may explain, at least in part, the problem of the unemployed female group.

Health certification for this area, therefore, must be considered an effective method of screening for syphilis.

Efficacy of Screening Methods

In order to gain some estimate of the amount of syphilis in Cumberland County, the persons who applied for health cards might be taken as a representative sample since they include all classes, races, and age groups in the county. By adjusting this sample group to the entire county population by age, sex, race, and occupation, using the 1950 population figures, it was determined that the prevalence of syphilis in Cumberland County amounted to approximately 1,900 cases (reactors) of whom 1,440 were Negro and 460 were white.

Through venereal disease control activities of the health department and private physicians, approximately 1,230 reactors were brought to disposition during the past year. Of these, 738 (60 percent) were found by the three above survey methods—diversified and industrial surveys and health certification. Of the remainder, 295 (24 percent) were discovered through the central activities of the venereal disease division, excluding surveys, and 196 (approximately 16 percent) were diagnosed by private physicians. Thus, the 1,230 reactors represent 64.7 percent of the total estimated reactor problem in Cumberland County.

As most of the reactors in the survey had late latent and tertiary syphilis, it would seem that the three methods of screening served primarily

to reduce the tremendous backlog of previously untreated or inadequately treated syphilis. And by screening 9,093 individuals from a population of 65,000 between the ages of 15 and 70 years, 738 reactors were discovered. In other words, screening 14 percent of the population by survey brought to light 39 percent of the estimated reactor problem of the county. This points to the efficacy of selecting certain population groups for screening techniques.

Venereal Disease, a Sociomedical Problem

Social data were obtained on persons tested in the 11-day industrial survey and analyzed in an effort to study the relationship of social instability and the acquisition of venereal disease.

It was determined that, by marital status, 21 percent of the total group (2,192 donors) were single; 66 percent were married for the first time; and 13 percent stated that they were separated, divorced, widowed, or married two or more times. The latter denotes a group with somewhat high marital instability. Whites and Negroes of both sexes showed equivalent percentages of marital difficulty.

These individuals were also questioned about history of previous venereal disease and civil court records such as felony. Ten percent stated that they had had venereal disease; 5 percent reported disfavor in court action; and 86 percent gave clear records for both difficulties. Here, a large difference appears between the races in that 19 percent of the Negroes previously had venereal disease and 8 percent reported a previous court record. These percentages for whites were 3 and 2 percent, respectively. Tables 4 and 5 illustrate the social significance of these factors on the acquisition of syphilis (reactor group).

These data suggest that marital instability is associated with multiple sexual contacts and

Table 5. Effect of promiscuity and antisocial behavior

Social data	Non-reactors (percent)	Reactors (percent)
Previous venereal disease-----	4.6	50.6
Previous court record-----	4.4	8.8
Neither difficulty-----	91.0	40.6

increased opportunities for acquiring venereal disease. Also, antisocial behavior and promiscuity (as shown by high percentages of previous venereal disease) are significant factors in the acquisition of venereal disease. The differences between whites and Negroes in antisocial behavior may account for the large differences seen in rates of syphilis between the races. This last correlation is significant statistically. A previous report from this area on venereal disease rates of prisoners also substantiates these data (11).

That this problem is not one of race per se is shown by arranging the various groups and plants tested in order of highest percentage of reactors. Unskilled worker groups contribute the most reactors and skilled laborers and professional workers, the least. College entrants (68 percent Negro) and teachers (83 percent Negro) were groups that demonstrated no positives. Furthermore, of 606 serologic tests taken of Negro freshmen at the Fayetteville State Teachers College in 1951, only 3 were positive, a percentage of 0.5.

Summary

1. Three screening techniques as employed by the Cumberland County Health Department are described. These screening measures may be adapted to most local health departments, as they aim at economy, long-range needs, and high prevalence groups of the community.

2. An 8-month period of selective screening of small industrial plants proved to be a diversified, yet highly profitable, screening method. About 17 percent of the donors were reactors.

3. Employing the State venereal disease survey team, large industrial plants were screened in an 11-day period and approximately 12 percent of the donors were reactors.

4. Health certification during the year screened 5,190 examinees who professed negative serologies prior to examination; about 5 percent were found to be reactors.

5. By screening a total of 9,093 individuals from a population of 65,000 (aged 15-70), 738 reactors were found. In other words, by careful screening of 14 percent of the population, 39 percent of the estimated total reactors in the county were found.

6. Disposition of the positive serologies found in the industrial surveys indicated a majority of late latent and tertiary cases of syphilis in the older age groups. A significant percentage of early latent syphilis was found, however.

7. Screening by health certification is an effective method of finding early cases of syphilis, as the examinees for the most part represent a high-incidence group prone to reinfection.

8. The effect of marital instability, promiscuity, and antisocial behavior on the acquisition of venereal disease is offered as a basis for selecting groups in the population for survey. Antisocial behavior, particularly, may help to explain the differences in rates between Negroes and whites.

Chronic Disease Mortality In Influenza Epidemics

Deaths from specific nonrespiratory chronic diseases have contributed to the total excess mortality during epidemics of influenza and pneumonia since 1935, a period when mortality from these diseases declined rapidly. Public Health Monograph No. 10, "Excess Deaths From Chronic Disease During Influenza Epidemics," considers this situation and reviews excess mortality from causes other than influenza and pneumonia in epidemics during the period 1918-34.

This paper is the fourth in a series on epidemics of influenza and pneumonia. The first three, published in *Public Health Reports*, include "Mortality from influenza and pneumonia in 50 large cities in the United States, 1910-1929" (1930), "Excess mortality from causes other than influenza and pneumonia during influenza epidemics" (1932), and "Trends and epidemics of influenza and pneumonia, 1918-51" (1951).

Weekly data from large cities in the United States during the periods 1918-34 and 1935-51 for 35 and 56 cities, respectively, are the basis for the study reported in Monograph No. 10. Weekly excess death rates from influenza and from other causes during the entire period 1918-51; total excess deaths during whole epidemics; concurrent peaks for deaths from influenza and pneumonia and from nonrespiratory causes during epidemics; total amount and percentage of excess mortality from influenza and pneumonia, and from nonrespiratory causes; distribution of mortality in four geographic regions; and diseases that account for excess deaths credited to causes other than influenza and pneumonia are discussed.

Public Health

MONOGRAPH 10

This summary covers the principal findings presented in Public Health Monograph No. 10, published concurrently with this issue of *Public Health Reports*. The authors are members of the staff of the Division of Public Health Methods, Public Health Service.

Readers wishing the data in full may purchase copies of the monograph from the Superintendent of Documents. A limited number of free copies are available to official agencies and others directly concerned on specific request to the Public Inquiries Branch, Public Health Service. Copies will be found also in the libraries of professional schools and the major universities, and in selected public libraries.

The State of the Nation's

Reports from the 51st annual conference of the Surgeon General of the United States Public Health Service and the Chief of the Children's Bureau with the State and Territorial health officers, mental health authorities, and hospital survey and construction authorities.

Report on Programs and Problems, 1953

1 Excerpts from a statement
by LEONARD A. SCHEELE, M.D.
Surgeon General of the
Public Health Service

Our country is still in a period of international emergency and national mobilization. The development of strong defense against the spread of aggression necessitates continued sacrifices by every American.

As public health workers, we have had an important share, from the beginning, in the program for economic and technical assistance to underdeveloped areas that need help to become strong allies. In sharing our knowl-

edge and skills, real progress has been made in the control of disease and the promotion of health.

Many State and local health agencies have joined with the Public Health Service in staffing these overseas health programs. Despite the general shortage of public health personnel, and although we have not been able to provide all the personnel our own Government and the struggling health agencies of underdeveloped countries have asked for, we have made a very good showing. These programs are so vital to the survival of a free world that the Public Health Service intends to tighten its belt even more so as to help meet their minimum staff requirements. We will continue to call on health agencies for help. (See report by Dr. Hyde, page 188, this issue.)

Health Material Requirements

During the past year, the Public Health Service has developed a smoothly running

organization to handle allocation of critical metals for construction of hospitals and health facilities. We are now concerned with the specialized technical staff work that must be done if civilian health supplies are to be available in the event of full mobilization.

This means that experienced and technically competent personnel must be available to work with industry in projecting potential demands and productive capacity 4 or 5 years ahead. The Defense Production Administration has delegated this responsibility to the Public Health Service. With the active cooperation of the health and medical supply and equipment industries, and the military forces, our Division of Civilian Health Requirements has made good progress in developing the basic data.

We expect in the immediate future to begin making similar estimates of facility requirements that would come with full mobilization. It will be important for State hospital survey and construction agencies to participate. We shall need to know what it takes to keep the existing hospital and health plant going; and what will be needed 4 or 5 years ahead for renovation and repair of buildings, replacement of equipment, maintenance of supplies, and so on.

Of special concern are items already in short supply, as well as those that would become critical under full mobilization. For example, already completed is a study of penicillin requirements, and our proposals for increased production have been approved by the Defense Production Administration. Recommendations soon will be completed on such items as surgical bandages, sutures, dental supplies and equipment, hypodermic needles and syringes, X-ray film and machines.

With these and to-be-developed data, the Public Health Service intends to keep abreast of the production situation so that civilian needs may be safeguarded in the face of increased demands and heightened competition for essential supplies and equipment.

Environmental Health

There are many encouraging signs of the emergence of practical solutions to some of the

“ONCE MORE the conference of the Surgeon General of the United States Public Health Service with the State and Territorial Health Officers—established by Congress as a statutory function 50 years ago—has assembled. In recent years, the effectiveness of this annual exchange of views has been strengthened by the companion conference of the Chief of the Children’s Bureau and by concurrent conferences with the State hospital and mental health authorities. These actions testify to the common interests of health administrators from all parts of the country and to their desire to work together as a united force for the protection and promotion of the Nation’s health.”

Thus the Surgeon General opened the 51st conference of State and Territorial health authorities held in Washington from December 8 to 11, 1952.

One of the important purposes of these meetings is to bring the health authorities up to date on important health developments and prospects on the national scene. Several reports which have more than transient interest are presented in these pages in abbreviated form. Other material stemming from these discussions will appear in later issues of *Public Health Reports*. Included here are excerpted reports from—

1. Dr. Scheele:	Page
Programs and Problems-----	174
2. Mr. Thurston:	
Federal-State Relations-----	181
3. Dr. Eliot:	
Child Health and Welfare----	183
4. Dr. Hyde:	
International Health Staffing--	188

critical problems created by new environmental factors in our rapidly changing society, at the same time that substantial progress is being made in long-established sanitation activities.

Radioactive Hazards

Steady progress has been made in the public health control of hazards incident to the use of radioactive materials and radiation-producing machines. Several State health departments already are operating radiological health programs—in recent months, for example, pilot programs have been initiated by the New Jersey and the California health departments. Progress also has been made on the Colorado Plateau in controlling radiation hazards inherent in the mining and milling of uranium.

Interstate Milk Shipping

The program for the certification of interstate milk shippers—recommended by the State and Territorial health officers for the past 8 years—has reached a point where additional support for the Public Health Service's share in these joint activities is essential. Despite lack of adequate funds, the Service has conducted during the past year a highly successful demonstration project. It has been shown that effective certification of interstate milk shippers can be achieved with the active participation of State and local health departments, agricultural agencies, and the dairy industry. If this modern method for the marketing of safe milk is to be extended beyond the limited area covered by our demonstration, all of the States, as well as the Public Health Service, will have to increase their activity.

Poultry Sanitation Code

The development of a poultry sanitation ordinance and code is going forward satisfactorily. This project is being conducted with full participation by the poultry industry and by law enforcement agencies.

Raw Garbage Feeding of Swine

The Executive Committee of the Association of State and Territorial Health Officers has been considering the need for appropriate legislation and supporting control measures in connection with the practice of feeding raw garbage to swine. The Public Health Service has been cooperating closely with the U. S. Department of Agriculture, and we believe that joint planning and action in this field will bring about better control of many swine diseases, including trichinosis and others of public health importance.

Up to now, our mutual efforts in this field have made headway slowly, because of lack of clear epidemiological data demonstrating the importance of trichinosis as a public health problem. Last summer's rapid spread, from coast to coast, of vesicular exanthema in swine, traced to the feeding of raw garbage, illustrates the hazards of the practice and its role in the

transmission of disease both to man and to domestic animals. This vesicular exanthema outbreak has stimulated reconsideration and brought forth new support from all quarters. Now is the time for State health departments to renew their cooperative efforts with their State agricultural agencies in legislation and control. The Public Health Service is tightening up its interstate action in this field, and we are prepared to provide States with technical and consultative service for their intrastate operations.

"Fringe Area" Housing

There is still a large residuum of substandard housing which presents basic sanitation problems—chiefly in urban and suburban areas, and not limited to "rural slums." "Fringe areas" still are growing faster than are our efforts to forestall serious health problems. Mobilization has brought with it a variety of housing sanitation problems. More than this, the morbidity and mortality rates from home accidents, the relation of housing conditions to cardiovascular disease, to arthritis and rheumatism, to the aging, and to many other conditions that stand among the Nation's unsolved health problems point day after day to the health agency's responsibility for action in the hygiene of housing.

Accidents in the Home

In home accident prevention, the Public Health Service and participating States have made some progress in developing the basic data essential for planning in this field. In fact, the time has come to pull together the recently acquired knowledge and experience and to evaluate what we have learned. Such an effort is planned for January when representatives of State, county, and municipal health agencies, voluntary organizations, and Federal agencies meet at Ann Arbor for a conference on home accident prevention.

Our Chemical Environment

The report of the House Select Committee to Investigate the Use of Chemicals in Foods and

Cosmetics focuses attention on the growing importance of the chemical environment as it affects human health. Much remains to be learned about the potential hazards, as well as the potential benefits, that may be inherent in the introduction and use of many new chemical compounds. With respect to our knowledge of the health effects of the chemical environment, we are just about at the same level of understanding as public health pioneers were three-quarters of a century ago in their knowledge of bacterial causes of disease. Our first steps, therefore, must be thorough research programs aimed at finding answers to fundamental questions.

Fluoridation Programs

In the advancement of dental public health, the fluoridation of public water supplies needs to be skillfully interpreted to the people of our communities. Although more than 500 towns are now benefiting from fluoridation, progress in applying this preventive measure has been impeded in some communities by misinformation. There have been some court actions, referendums, and opposition by groups and individuals.

Such situations are not uncommon in the history of public health progress. The early efforts to install chlorination of water supplies met with opposition, sometimes with unfounded fears of "poisoning." Again, we are called upon to exercise a high degree of public health statesmanship. The skeptics must be convinced that our epidemiological and laboratory studies are valid and that the benefits of fluoridation are not to be discarded lightly in the face of uninformed opposition.

Communicable Disease Control

New disease entities are being identified; new agents for prevention and control of well-known infections are being tested; and the problems of identifying the etiologic agents in unusual outbreaks are increasing—in short, future progress in the control of communicable disease depends upon the efficiency of our epidemiological and research techniques. In disasters or enemy attack, success in protecting

large populations from rapid spread of disease depends upon a well-organized, highly efficient, nation-wide epidemiological service.

During the past few years, the Public Health Service has been emphasizing the epidemiological approach in its communicable disease control and microbiological research undertakings. The sectional research program in microbiology set up in the National Microbiological Institute and the epidemic intelligence service set up in the Communicable Disease Center are the two major contributions of the Public Health Service to the attainment of such an organization. The institute and the center are, of course, developing their programs together as a team.

Emergency Reserves

The Public Health Service has made repeated attempts to build up a more extensive and vital inactive Reserve Corps, particularly for active duty in the event of full mobilization or disaster and to provide officers for assignment to the States for duty in defense-impacted areas. We have been handicapped by lack of funds.

We are, however, about to launch an experimental expansion of the inactive Reserve Corps in the engineer component. The idea is to have available a reserve of engineers who could be called to duty in the vicinity of their usual place of employment. Recruitment will be largely from sources other than State and local health departments—industries, public utility companies, universities, and units of governments having engineering personnel.

We plan to use our present engineering staff as recruiting agents and to keep inactive reservists informed on developments in environmental and general public health fields. Engineer reservists are expected also to have opportunities for active duty—from a few weeks as special consultants, to a year or two on special missions. Later we hope to conduct special training along the lines employed by military reserve organizations. This demonstration effort should provide experience that will be of value in the eventual development of an expanded inactive Reserve in components other than engineering.

Sectional Research Program

The aim of the sectional research program is to encourage laboratory and epidemiological research on infectious agents through the operation of a nation-wide network of regional and coordinating laboratories especially skilled in microbiological investigations.

At present, 98 laboratories, organized in 11 sectional groups, are participating. More than 10 percent are in State and local health departments, and representatives of several State laboratories are on the advisory committee helping us to develop this program. The Public Health Service has awarded research grants to those laboratories requiring aid in order to participate, and next year we hope to increase the amount available for these grants.

Epidemic Intelligence

The companion epidemic intelligence service has completed its first full year of service. We have been encouraged by the results and by the cooperation which has been extended by the State and local health departments, the schools of public health and medicine, and others who have teamed up with us. A second group of epidemiologists have completed their initial training at the Communicable Disease Center and are now in the field, bringing the number of medical officers in the intelligence service up to 32. By expanding this corps, and by stepping up various types of laboratory and field research, the Public Health Service is better prepared to discover and combat disease outbreaks, whatever their origin and wherever and whenever they occur. We stand ready to answer the call for epidemic aid from any quarter of the Nation.

Disease Reporting

Efficient morbidity and mortality reporting is a fundamental requirement in the investigation and control of communicable disease. The increasing strength of State activities in vital statistics and morbidity reporting is evidence of progress in this field.

Plans are going forward for an expansion of State and national reporting of animal diseases.

Although collection of data on animal diseases is a function of the United States Department of Agriculture, the Public Health Service has offered consultative assistance in the planning stages because of its many years of experience in the reporting of human diseases. I hope that the State health departments will offer similar assistance to their State agricultural agencies.

Poliomyelitis Prevention

Reports by several investigators within the past few months indicate that we may be on the threshold of development of one or more useful immunization agents for poliomyelitis (see *Public Health Reports* for January 1953, pp. 105-107). Much research remains to be done, but the immediate potentialities of gamma globulin pose major practical problems for Federal, State, and local health agencies and the medical profession. Close and active cooperation in the development of policies and procedures relating to blood collection, serum processing, and allocation are required of all hands.

Venereal Disease Control

By the middle of 1953, venereal disease control programs will have attained almost complete conversion to out-patient treatment of syphilis. This is indeed a triumph and one in which all of us share. It is the result of research, pharmaceutical production, and public health and private medical practice. Now every private physician can be an efficient venereal disease control officer, giving ambulatory treatment to patients in his office, while State and local health departments maintain the important supporting services of case finding, contact tracing, referral, treatment of many patients unable to pay for private care, and education.

State health departments are establishing about 70 prevention and control centers in strategically located urban clinics. They aim to provide the best in venereal disease diagnosis, treatment, epidemiological services, and education. From them will radiate services to physicians, local health centers, hospitals,

and social agencies in the area. There are here, also, opportunities for professional training in cooperation with universities and medical schools.

Chronic Disease Control

In tuberculosis, cancer, heart disease, diabetes, arthritis, and other chronic diseases we might well aim for levels of control that involve every practicing physician giving ambulatory treatment, either preventive or curative, in his office. Thus as a key element in its chronic disease effort, the Public Health Service continues to support an unremitting search for case-finding techniques that may be applied on a wide scale and for therapies that may ultimately be placed in the hands of the general practitioner as well as the specialist.

Certainly, facing up to the problems of chronic disease and an aging population, public health agencies need to encourage and develop many new types of partnership. There is strong support for chronic disease control and for health services to the aging. Yet State and local health services in most of these fields are scanty and scattered.

While new techniques for chronic disease control and hygiene of the aging remain in a twilight zone between experiment and widespread use, it may be that a "bridge" type of community institution with research, educational, and limited service functions is needed to speed the sound application of scientific advances. (See description of this type of institution in *Public Health Reports* for January 1953, pp. 8-9.)

Rheumatic Fever Prevention

All interested in health have long looked forward to the day when a sound preventive program against rheumatic fever could be proposed and endorsed. Recently, the American Heart Association and its affiliated Council on Rheumatic Fever and Congenital Heart Disease formed a committee on prevention of rheumatic fever. This group proposes, essentially, two main lines of action: (1) early and adequate treatment with penicillin of all cases of streptococcal infections; and (2) long-

term prophylactic use of sulfadiazine or oral penicillin in rheumatic patients. (See *Public Health Reports*, January 1953, pp. 12-15, for the full text of the statement.)

These recommendations of the leading specialists in this field represent a milestone on the road to control of rheumatic fever and its crippling companion, rheumatic heart disease. Implementation of the community programs which makes such control possible should be given high priority.

Rehabilitation

At the 1950 meetings of this conference it was recommended that the Public Health Service and the State health agencies undertake studies of the public health aspects of rehabilitation. We are now preparing the final report of a Public Health Service committee and task force on rehabilitation which was formed last year with the cooperation of the Office of Vocational Rehabilitation.

Community action for the improvement of rehabilitation facilities and services is widespread. Spurred by Federal aid for the permanently and totally disabled, many communities are planning and developing service programs with a minimum of health department participation. Unless State health officials move quickly and think through their responsibilities in this field, they stand to lose opportunities for significant leadership in improving health services generally and particularly in the fields of chronic disease and impairment where we already have operating programs.

Hospital Licensure

State health and hospital agencies increasingly are involved in the licensure of hospitals and related institutions. At their request, the Public Health Service has undertaken a compilation of existing regulations for institutional licensure. Guide materials for the development of licensing procedures and techniques are being prepared.

Licensure as a phase of hospital and related institutional care is destined to come into greater prominence as programs for the aging,

for convalescent care, and for rehabilitation expand. The subject requires a great deal more study, but such study requires more funds than the Public Health Service yet has had to devote to it.

Manpower Shortages

The shortage of professional and technical personnel which has engaged our attention for two decades continues to be a serious problem. Trained workers, never available in numbers adequate to meet the needs of organized services and institutions, are in steadily increasing demand from a number of sources. We must, therefore, make strenuous efforts toward more effective utilization of our present supplies of professional and auxiliary health personnel. It is highly probable, for example, that a number of duties now performed by physicians could be delegated to nonmedical personnel.

Critical evaluation of all activities, constant and intensive recruitment, in-service training, careful consideration of salary levels, opportunities for advancement, and satisfying work experiences—taken together—constitute main weapons against the current shortage. Essentially, this means that we must try to get well-qualified workers into public health, or workers with the potentiality for high qualifications, and we must make our field a career service for them—one which they need not and will not leave for another.

In nursing—a particularly difficult area—several State health agencies during the past year have been active in the conduct of nursing surveys. Some hospital divisions in State health departments also have taken the initiative in stimulating hospitals to evaluate the utilization of nursing personnel. The coming year should see increased activity in both these fields.

Re-examining Local Services

We in the Public Health Service believe that the time has come to re-examine carefully the entire concept of, and structure for, the delivery of community health services. The present pattern has served its purpose well. However, new forces have emerged in the total social

fabric. We are confronted with many new problems. Marked changes have occurred in the physical environment. The general standard of living has improved markedly. There are better means of communication and transportation. New scientific bases are available for prevention, diagnosis, and treatment of illness. There is a wider public understanding of personal and community health problems.

Are we taking advantage of these many new technological, social, and economic forces to make available the best possible health services at the lowest per capita cost? Are we organizing and administering programs that merely maintain the status quo, or are we getting down to the "grass roots" and finding out what precisely are the health needs and the best means of meeting them? Are we experimenting with new techniques?

To illustrate: In approaching a study of the amount and kinds of nursing service required to meet the minimum needs of local health departments, the Public Health Service has run head on into the basic fact that to consider the needs of a single type of service is not enough. The fact is, we have too long fractionated our approach. It is not enough merely to extend the study to cover other types of public health personnel. We must go much deeper.

Today's public health problems require a wide range of professional skills, facilities, and services. We have become increasingly aware that the newer programs do not always fit into the traditional structure. Many local health organizations as now constituted cannot cope with the problems. Local health organization is indispensable, and it must be strengthened. We must learn new ways of organization as well as new operating techniques.

Any new approach to local health services must be carefully planned after well-conducted studies. Such studies must be so designed as to yield results applicable to the whole field of public health, not merely to the solution of discrete problems. They must be of sufficient scope and longitude to insure valid conclusions. They must be focused more upon the human community than upon the professions which serve the community. They must draw upon the social sciences for their design, methodologies, and conduct.

The need for such appraisal of current practices and for the development of more effective and economical methods for different types of communities is of vital concern to all health workers. The Public Health Service hopes to begin the difficult first step of such studies—the planning—in the near future. But we cannot, and we will not, promise any hasty “appraisal” or quick results. But we shall do our best to add some useful knowledge to the science and art of public health.

Report on Federal-State Relations, 1952

2 Excerpts from a statement
by JOHN W. THURSTON
Deputy Administrator of the
Federal Security Agency

This meeting is significant because it is indicative of growth in health programs and responsibilities. It is also significant because it demonstrates maturity in Federal-State relations—serious, cooperative consideration of nation-wide health problems.

Back of the growth lies a long history of cooperation, the development of a system for recognizing, meeting, and solving health problems. We have created a structure that is enduring and that has met the test of time. The machinery for action-in-partnership is here and it works. It has become a part of our social heritage, extending beyond individuals and beyond shifts in political alignments. The only real danger we face is to fall victims of the twin evils of arrogance and complacency—to lose that sense of hopefulness and vision and hard work that brought us where we are today.

Results of Partnership

The results of the partnership have been substantial. Even as we reflect on the achieve-

ments of the past, however, we are wrestling with the problems of the present, in part created or intensified by earlier victories. The changing environment, the general aging and mobility of our population, the swift pace of industrial expansion bring us face to face with new problems. Health problems today are much more subtle and complicated than they were in the past.

The greater the awareness of the new factors, the more effective will health services be. Health workers must ally themselves with other social forces in the local and national community. The partnership must not only grow stronger between the various levels of government—local, State, and Federal—but must also branch out laterally. Adequate health services in the future call for genuine integration with related social programs, such as welfare and rehabilitation and education, and for close rapport with other community services that affect health, such as housing and community planning.

The Federal-State partnership is based on respect and trust, on the recognition of individual rights and mutual responsibilities. The flow of power is a natural one, from the individual citizen to his local community and then to his larger community, the State and the Nation. The interrelationship between the citizen and his government, and within the various levels of government, is delicate and subtle, yet strong, like a fine fiber.

An American Invention

The structure that binds us together is, in fact, unique in man's governmental efforts. It is an American invention, rooted in our social fabric and peculiarly suited to our geographic needs. It has developed out of a combination of circumstances—our pioneering traditions, our strong community bonds, our patterns of emerging social obligations. At its base is a federated system of government—a system of local, State, and Federal authorities—with each member of the partnership having its own set of duties, powers, and obligations.

The American federated system is also unique in its sources of strength and its possibilities for action. It preserves and extends

local independence and at the same time permits national concentration on national problems. Our citizens have different loyalties without necessarily having conflicting loyalties. We meet national needs best when local resources are strongest.

It is true that problems may not always be the same. The needs of some States may differ somewhat from the needs of other States, and local problems may not always be comparable to those of the State. But there is a core of problems that require joint undertaking, that confront all the people of the United States. And these problems demand the united efforts of our Federal-State-local system.

The result of the system then has been a fusion of effort which helps us to pull together our resources instead of scattering them or instead of quarreling over them. It is this kind of teamwork that has enabled us to undertake cooperative endeavors, to share ideas, resources, and facilities for a common national goal.

Unity and Responsibility

This is not to imply that all our endeavors have been marked by complete harmony. Nor would we want to pay the costs of such a harmony, the costs of smugness and stagnation. We have had differences, but they have been honest differences. But from these differences, from the hammering out of compromises, has come greater understanding and a higher kind of unity.

When we come to the differentiation of responsibilities, we find that certain broad categories of responsibility fall, quite typically and quite naturally, to the Federal partner, just as others fall to the States and the communities. For example, it is an accepted obligation of the Federal partner to conduct research and experimentation in new health techniques; to develop and set nation-wide standards; to collect national statistics of various kinds; and to meet problems which are interstate, international, or so new or so fluid that no State or local agency could possibly undertake them.

Financial aid is, of course, an important type of assistance offered by central to local governments. But it is by no means the only, or even

the most important, kind of aid. I think the grant-in-aid principle is firmly established in this country; it is one of the buttresses of our federated system of government. It is to be expected, however, that at any particular time one member of the partnership may be stronger in resources than another, and that there will need to be a continual balancing of forces in the interests of greatest economy and productiveness.

More important than the financial aid is the necessity for all groups to do their share in a unified, constructive way. The Federal-State health system is not a matter of giving but a process of sharing.

Trail Blazing by States

Sometimes it is charged that the Federal Government dominates the States. I know something about the Federal regulations governing grants for health purposes. And I see nothing in the Federal-State system that prevents any State from seizing the initiative and blazing the trail in new health programs. I do not think the States have been stifled because they have been the recipients of Federal grants. I do not know of many bold experiments or new programs that have been vetoed in Washington.

Certainly there have been experiments, new programs, new techniques. There will be more. There must be more if there is to be real progress. The flexibility of the Federal-State structure, its adaptability for many kinds of uses, leaves room for a wide variety of new programs, for administrative and technical pioneering.

This very meeting is evidence not of Federal coercion, but of healthy give-and-take discussion and of general agreement on goals to be reached and methods to be followed. Here we find a core of dedication, of good will, of social conscience, and professional competence that will enable this Nation to attain new levels of health.

I think we can all take pride in the health structure we have built, in our strong chain of health defenses. It has carried us a long way in a relatively short span of years. Despite calumnies, despite set-backs, despite the fears of some, it will carry us much further. I am

confident that the people, as well as the health professions, will be satisfied with no less in the future.

Report on Child Health And Welfare

3

Excerpts from a statement
by MARTHA M. ELIOT, M.D.
Chief of the
Children's Bureau

The United States is becoming a nation of old people. While it is true our aged are increasing in number, as a nation we are maintaining our youth. We are actually growing younger faster than we are growing older.

During the past decade, while the population over 65 years of age increased 37 percent, the population under 5 grew 55 percent. These children now are increasing our elementary school population in great numbers. Soon the effect of this increase will be felt in the high schools.

This fact has many implications for health, welfare, and education programs for children and youth. It means that during the current decade, we will be facing new and ever greater responsibilities in providing services for them.

Today in the United States there are nearly 48 million children under 18 years of age. The characteristics of this child population are of significance to us.

In rural areas live 43 percent of our children. Almost one-half of all children belong to families with incomes of less than \$3,000 a year.

An impressive reduction has taken place in infant and maternal mortality for the country as a whole. There are, however, many counties, largely rural, which lag a decade or more behind the more metropolitan counties. The majority of the counties where higher infant mortality rates prevail are in the southeastern and southwestern parts of the country, where some of our most economically depressed families live, many of them migratory workers, Negroes,

Spanish-speaking people, Indians. These people are living under serious disadvantages. They need our continuing help.

The needs in such areas are basic in character—adequate nutrition, housing, sanitation, public health services, maternal and child health services. Equally important are the acceptance and utilization of these services by a population which often does not understand too well what they are.

The Premature Infant

The leading cause of infant mortality throughout the Nation is prematurity. At least 7 percent of all live-born infants are premature, and about 60 percent of deaths in the first month of life are associated with prematurity. The inclusion of birth weight on birth certificates by the States is now making it possible, through the matching of birth and death certificates, to increase greatly our information about prematurity.

For over a decade health departments have done considerable educational work in the area of prematurity, lending incubators, providing consultation to hospitals, giving nursing care in the home, and providing opportunities for nurses and physicians to obtain additional training in this field. These efforts have been accelerated and extended in the past 5 years.

Among the newer significant developments has been the increase in the number of State health departments which are working with hospitals and medical schools in developing centers for the care of premature infants—centers which serve as the focal point of community programs for premature infants. Such programs are demonstrating that mortality among prematures can be reduced appreciably. These good results are even being extended to infants weighing less than 2 pounds.

The birth of a premature infant constitutes a serious economic problem for almost every family when it happens. The average duration of hospitalization is 30 days and the average cost per infant is almost \$500, and, naturally, the smaller the premature, the higher the cost. Clearly such a cost added to the cost of maternity care is often calamitous to families with low incomes.

That 16 State health departments are assisting families in bearing the costs of medical and hospital care, at least in demonstration areas, is encouraging. The development of such programs, though still in their inception, is among the outstanding accomplishments of health departments in recent years.

The increased knowledge about prematurity gained from these programs, together with an appreciation of what the financial burden of premature birth means to families, is leading State health departments to give more consideration to the possibilities of reducing the incidence of prematurity.

This involves, in the first place, extending prenatal care facilities so that women can have good care during pregnancy. Women who have poor care or none are about three times as likely to have a premature baby as those who have good prenatal care. The major known causes of prematurity are complications of pregnancy, which are prone not only to cause premature labor, but also to decrease the chances of survival of infants born prematurely. For these reasons, several States which have been active in caring for premature infants are also directing their attention to maternity programs, increasing prenatal care services, and providing medical and hospital care for women with complications of pregnancy. Herein lies the greatest possibility of reducing the incidence of prematurity, of lowering the costs of care for premature infants, of reducing the number of blind infants with retrolental fibroplasia, and of lowering fetal and infant mortality.

School Health Services

Health services for children of school age constitute a considerable proportion of the maternal and child health programs of many States. Health and education departments are giving greater attention to the use of screening techniques for finding children in need of medical attention and to assisting these children in securing the services they need. If less time were spent on frequent examinations of children in the schools and more time on screening and follow-up, on medical consultation to the

school, and on the utilization and development of local resources for diagnosis and treatment, most school health programs would undoubtedly be more productive of good results.

The pamphlet "Better Health for School Age Children," prepared by a committee of staff members of the Children's Bureau, the Office of Education, and the Public Health Service, has been widely distributed. Through its clear and specific statements on the subject (summarized in the November 8 issue of the *Journal of the American Medical Association*), it makes a real contribution to the literature in the field.

The Rural Problem

Earlier I referred to the fact that children living in rural areas are at a disadvantage in some respects. Medical specialists are for the most part concentrated in urban areas. Children in rural counties, moreover, receive considerably less medical supervision than those in or near cities. But it is particularly with regard to specialized services, such as those for premature infants and crippled children, that rural children are at a disadvantage. With our greatest medical skills concentrated in the teaching medical centers, one of our major problems is to help children in rural areas have the benefit of such skills.

State maternal and child health and crippled children's programs have pioneered in bringing to rural areas specialized services for certain groups of children, such as premature infants and children with orthopedic and other handicaps. In recent years, in addition, several health departments have developed pediatric consultation clinics in rural areas which bring at regular intervals the services of a well-trained pediatrician associated with a teaching hospital to the area. Not only are significant services thereby provided children who are referred for consultation by physicians in private practice and by public schools and other community services, but the clinic also serves a teaching purpose in the consultative relationship between the pediatrician and local practitioner. Children in need of further diagnostic work or treatment which cannot be obtained locally are provided these services in an urban teaching hospital which in this respect takes

on a regional function. This relationship of the local pediatric or special clinic with the teaching hospital is a most important factor in raising the quality of care. Extending arrangements such as these would greatly improve the quality of care for children throughout the country.

Crippled Children

State agencies have continued to make gains in the past year in extending services for crippled children, a group for whom there is much support from the public. Parents' groups particularly have become much more active in recent years in supporting these services. Although some of these groups have tended to emphasize certain conditions, they are nevertheless a constructive force which can be of great assistance to all of us in program development.

States are experimenting, too, with new types of services. Since the beginning of the epilepsy demonstration program in Maryland in 1950, some seven or eight other States have also begun epilepsy programs. Other States are planning them. Through the active participation of organized public health services, the benefits of research in therapy can be brought to epileptic children all over the country.

Progress is also being made in the further development of the regional congenital heart disease program. California's program is now in operation serving the far West, Alaska, and Hawaii. The program centering in Illinois is under way and plans for Texas and Maryland have been approved. Programs such as these are representative of the dynamic nature of public health today and its readiness to experiment with new methods of providing service.

Interesting developments are also taking place in services for children who have cleft palate. This group of children has been included in virtually all of the State crippled children's programs since the passage of the Social Security Act, but recently, in a number of States, some of the traditional concepts of treatment are being questioned and modified. Again, the necessity of considering the child first as a growing individual and second as one with a defect in a particular part of his body is being emphasized.

Surgery for cleft palate is not the solution for all children. For those who do need surgery, careful consideration must be given to the age at which this will be done. Many children, without surgery, have satisfactory speech with the aid of a prosthesis. Too many children who have had several operations still do not have a closed cleft or satisfactory speech.

One of the most encouraging aspects of the newer concepts in this field is the recognition that the care of the child with a cleft palate is not the province of the surgeon alone. Some of the best work is being done in those centers where each child is carefully studied by a team—the plastic surgeon, pediatrician, orthodontist, prosthodontist, speech therapist, medical social worker, public health nurse, and others—which considers all the aspects of the situation and reaches agreement on what is the best procedure to be followed for this particular child. Such teamwork offers new opportunities for greatly improved services in a technically difficult area. Opportunities for training in this field are being offered through the University of Illinois Medical School and services for crippled children in Illinois.

Children of Migrants

A different problem, that of children of migratory agricultural workers, demands attention. Their number varies with the season of the year, but it ranges from 250,000 to 1,500,000. These children are, economically and socially, the most depressed group of children in the whole country. Few stay long enough in any one place to call it home. They grow up without having enough of anything. They lack food. They lack adequate shelter, clothing, medical care, and education. Sickness and mortality rates are high among them. These children contribute to the high infant mortality rates in the Southeast and the Southwest. The problem of the families to which these children belong is fundamentally an economic one. Its solution lies in some far-reaching social and industrial measures. Until these measures are undertaken, attention must be directed to the serious health problems of the children. Some States are already helping these families, but in many localities their needs are still unmet.

To be effective, not only must the several agencies involved within a State make a concerted effort; there must also be cooperative interstate efforts. Among the measures that need to be taken are: adequate housing; environmental sanitation; health and medical care services for infants, young children, and expectant mothers; health education that will reach the different cultural groups; and interstate cooperation.

One of the principal causes of death among infants and children of migratory workers is dysentery, a fly- and water-borne disease. Adequate sanitary engineering, fly control, and screening of houses will do much to reduce this mortality. Even as we help peoples in Europe, Asia, and Latin America to adopt sanitary measures, we must help people in some sections of our own country to do the same.

Bringing adequate health services to these families is not a simple matter. One of the basic problems in providing services for migrants is the lack of coverage by local health units. When we have the basic services in public health that we need in rural areas, at least some of the migrant's health problems will be solved, or the mechanism will be available for solving them. I would give the strengthening of the local health units a very high priority among our public health needs but even with basic coverage attained, the job of increasing services suddenly for large numbers of people for a short period of time is a difficult one.

Mobile units may have to be considered. Probably additional staff—physicians, nurses, medical social workers, nutritionists, health educators—will be needed to provide individual services and to make arrangements with social agencies for child welfare services. In view of the poor resources these families have, the provision of medical and hospital care must be included.

Provision of day-care centers would constitute another constructive health, as well as welfare, measure. Since both parents and older children in these families usually work, young children are commonly left pretty much on their own. In a few States, day care is being provided, but additional financial support is needed if any headway is to be made in the provision of this service.

State and local health and welfare departments which have the basic organization to do the job must take the responsibility for the administration of health and welfare services to meet the needs of migrants. Migrants should not be set off from the rest of the population but should be enabled to participate in all community services to the fullest extent possible.

Juvenile Delinquency

One of the most serious byproducts of the general insecurity brought about by periods of national and international unrest is the marked increase in juvenile delinquency. Adolescence is a period when youth is naturally in revolt against the adult world. In seeking their own place in the world and establishing their identity, adolescents tend to band together. They may easily fall into antisocial patterns of behavior with which we are familiar in this country. They may also be exploited as in totalitarian countries. It is our responsibility to understand the behavior of adolescents and to help direct it into constructive channels.

Because this problem is becoming increasingly serious, the Children's Bureau during the past year has been giving a majority part of its attention to it. We have established in the division of social services a newly organized juvenile delinquency branch. A special juvenile delinquency project is being financed through private contributions to the Child Welfare League of America. This special project is working closely with the Children's Bureau. We have had a series of conferences with many leaders in this field and with public and private agencies, one of the most recent being with the National Health Council. The Children's Bureau has published several factual pamphlets about juvenile delinquency, and the December 1952 issue of *The Child* is entirely devoted to this subject.

These are a few of the facts we have brought to public attention:

About 350,000 children were referred to the juvenile courts in this country in 1951. Most of these boys and girls are 15 to 17 years of age.

About 1,000,000 were picked up by the police for delinquent behavior.

The number of delinquent children seen in

juvenile courts has increased 19 percent between 1948 and 1951.

Some 50,000 to 100,000 children are detained each year in local jails, often with adult criminals.

As a result of the increased birth rate, it is expected that by 1960 there will be 45 percent more children between 10 and 17 years of age than there were in 1950. Even if the rate of delinquency does not increase, the number of children picked up by police may rise to 1,500,000 by 1960.

We can do much to prevent delinquency, and we can provide juvenile delinquents with the treatment they need, much better today than in the past.

The Mentally Retarded

Another important problem is becoming of increasing concern to public agencies, that of the mentally retarded. The parents of these children are increasing their efforts to secure help for them. In public programs, when both funds and personnel are short, priorities must be given to some activities. Unfortunately, the mentally retarded are not high on the priority list. Yet as we learn more about these children and their problems, we find that many with help need not be nonproductive nor a financial drain. Access to good diagnostic services is a first step in a constructive approach to the problem. Let us hope that in the near future, health, education, and welfare agencies can give consideration to how their resources can be utilized best in helping these children and their families.

Personnel Shortages

The need for personnel continues to be a major problem and probably will continue to be for some time. Progress, I believe, is being made in improving the teaching of preventive medicine and public health in medical schools so that more medical students will be graduating with some knowledge of the modern concepts and services of public health agencies and an increased respect for public health. Because of this shortage of personnel we continue to emphasize the need for increasing oppor-

tunities for training. The principal means of doing this is through the provision of adequate stipends for fellowships. There is need to give some long-term fellowships—2 or 3 years—to assure fuller training in the many aspects of child health that will be required by future leaders in our maternal and child health programs. This is essential if we are to maintain our gains of the last few years.

Evaluation of Services

Large sums of money are spent by Federal, State, and local governments to promote children's health and welfare. The needs of children and their parents for aid in these respects are great, and it is to the advantage of all that the physical and emotional health and social functioning of children and youth be the best possible. That evaluation of health and welfare programs and practices is needed is obvious.

To carry on evaluation studies is a huge and long-range task. The Children's Bureau plans to provide research consultation to those States requesting it in one or another of the following program areas in 1954:

1. Foster care of children who are homeless, neglected, or for some other reason need care outside their own homes.
2. Adoption services.
3. Delinquency control and services to delinquents.
4. Health supervision of children through child health conferences or school health programs.
5. Services to crippled children, especially those services that are not medical.

There is a limit to the amount of consultation services the staff can give. As a first step in undertaking such studies, a report on the methodology of research is being prepared.

The various subjects touched on here, though briefly, demonstrate the broad interest of the Children's Bureau in children and the close relationship between child health and child welfare. The physical, social, and emotional problems of children are inseparable. Only as all the professions involved work together in a genuine spirit of service can the interests of children be served in the way we all want them to be served—to the highest degree possible.

Report on International Staffing

4

Excerpts from a statement
by HENRY van ZILE HYDE, M.D.
Technical Cooperation
Administration

The resolution of the Association of State and Territorial Health Officers (see page 189) constitutes clear recognition of the fact that from now on the United States is inextricably involved in the health problems of the world. It further recognizes that this is a phase of public health which is not exclusively a Federal responsibility—not solely a responsibility of the Public Health Service, nor of the Department of State nor any other Federal agency. This statement gives clear recognition to the fact that American health leaders, at all levels, must from now on encompass a world responsibility while discharging their domestic responsibilities.

Your resolution is encouraging not only to the Federal agencies concerned with international health, but to the World Health Organization, the Pan American Sanitary Bureau, and, more particularly, to those countries that need your leadership and assistance in improving their health. It will serve as a beacon to them in searching the way out of the morass of ill health.

Mobilizing State Leadership

For some time we in the national agencies have been seeking ways whereby the full force of American public health leadership could be brought to bear upon the problems of health abroad. We are well aware that leadership in public health in this country resides to a very large degree in the State and local health departments. A practical question is: How can we avail ourselves of your leadership and the leadership under your influence in tackling international health problems?

The Public Health Service is taking a first step toward an answer. Taking into account that the international phase of public health is a long-term responsibility with workaday aspects, the service is transferring its Division of International Health to the Bureau of State Services. This move should integrate more closely and bring into proper balance within the Service the domestic and international phases of its total public health responsibility. It is hoped that this move will strengthen the intimacy of the relationship of the Service to the State health officers in discharging international responsibility. It will provide, likewise, opportunity for full utilization of the regional offices in international work.

Approaches and Principles

How can we mobilize full strength in this program? How can we bring it fully to bear on the international problem? We need to seek new ways and to seek these together. The problem has been discussed with a number of State health officers. In every case we have found enthusiasm and interest, with reservations only concerning ability to contribute as largely as the State would wish.

There are certain underlying principles governing the program that should be understood:

1. It is truly a joint endeavor with each country, not a unilateral effort.
2. The specific content of each country's program is determined jointly with the ministry of health in the country concerned. It is not laid out in Washington nor by the Americans in the field.
3. Program can be influenced most effectively in the field, by field visits, when the annual program is being developed. It would be brash to attempt to mold or veto programs at great distances, particularly when they are to be carried out in a foreign setting.
4. The United States is furnishing leadership, not the mass of workers. Quality, not quantity, is required—competent, experienced public health leaders to give direction to pro-

Whereas, the Association of State and Territorial Health Officers recognizes the importance of improving world health as a sound basis for insuring world peace, and

Whereas, the United States of America has achieved pre-eminence and leadership in the field of public health, largely due to the training and experience of all public health personnel in State and local health departments and the U. S. Public Health Service, and

Whereas, by cooperation in the extension of modern public health services to other countries in the world, as well as the interchange of views and experience through the assignment abroad of trained United States personnel there has de-

veloped a better mutual understanding of the problems concerned and distinct improvement in local and domestic health conditions: And, therefore, be it

RESOLVED, *That the Association of State and Territorial Health Officers, assembled in annual sessions at Washington, D. C., December 8-11, 1952, hereby pledges its continued interest and support to the international health programs now being carried out and strongly recommends that State and Territorial health officers encourage and, by active participation wherever possible, extend this great movement in international health, and thereby help to promote the spirit of good will and peace throughout the peoples of the world.*

gram development and to train and direct indigenous workers.

Personnel and Objectives

In the 18 countries in Latin America, where the program is most advanced, there are fewer than 100 American technicians directing programs involving over 6,000 native personnel. In the Near East, African, and Asian areas, there are now in the field of health and sanitation about 95 technicians under an authorized budget providing for 158 positions. Although some increase of the authorized budget might be forthcoming, it is not expected that the number of personnel required will skyrocket.

The object of the program is, of course, to build strong, permanent, self-supporting national and local health services. It is necessary first to create widespread public demand for such services—a demand sufficiently strong and clear to constitute effective political pressure. Such a demand can be generated through sufficiently widespread, successful demonstrations of effective health services. At the same time, it is necessary to train indigenous technicians, both professional and subprofessional, and to develop true public health leadership within

the country. The program is, thus, basically one of demonstrations and training. It is a program that requires competent, experienced leadership abroad working under the stimulation and broad guidance of the best at home.

A Pioneering Step

In seeking means for full participation in this program, an important pioneering step has recently been taken in the signing of a contract between the Commonwealth of Massachusetts and the Technical Cooperation Administration of the Department of State. This contract establishes the principle of cooperation and sets up a working method that is already providing action. The principles inherent in it are important.

The contract establishes a special relationship between the Department of Public Health of the Commonwealth of Massachusetts and the Technical Cooperation Administration, with particular reference to the Point IV health program in Pakistan. The contract, in its preamble, recognizes the fact that the personnel and facilities of the Department of Public Health of Massachusetts are particularly well suited for participation in the activities contemplated under the program for the improvement of public health and sanitation in a rela-

tively underdeveloped country. The Commonwealth on its side recognizes that its personnel under such an arrangement will gain invaluable training and experience in work abroad.

Article I defines the functions of the Department of Public Health of the Commonwealth as follows: (1) to make available the ability and services of the commissioner of public health as chief consultant to the Government of Pakistan and the Technical Cooperation Administration in the development of cooperative programs of public health in Pakistan; (2) make available the abilities and services of such specialized personnel of the Department of Public Health as the commissioner may consider advisable to serve as additional consultants; (3) be responsible, in cooperation with the appropriate officials of the Government of Pakistan or other participating countries and the directors of United States technical cooperation in such countries, for the planning of cooperative programs for the development of public health; (4) endeavor to provide, as expeditiously as is practical, technicians to perform services as the needs of the cooperative public health and sanitation programs in Pakistan or other participating countries require and as requested by the Technical Cooperation Administration; (5) assume responsibility for participating in the selection of candidates for Technical Cooperation Administration grants for training.

Certain funds are transferred to the Commonwealth of Massachusetts in order to enable it to carry out these functions.

TCA-Massachusetts Team

It is important to notice that this contract sets up a partnership between the Technical Cooperation Administration and the Commonwealth of Massachusetts' Department of Public

Health—a partnership dedicated to assisting a specific country through a cooperative program. The State will have a major voice in the form that such a program might take. It will give intellectual leadership, stimulation, and direction. Staffing will be only a part of the job. Under such a contract State personnel can be assigned to foreign duty without loss of rights within the State service. Such personnel can continue to grow under the leadership and direction and observation of the State health officer.

The contract is not so rigid as to exclude other methods of employment. Particularly, when it is advantageous to do so, the personnel may be commissioned in the Reserve Corps of the Public Health Service. Whether in the employ of the State or commissioned, personnel when on assignment to the foreign country will work as an integral part of the Point IV mission to the country, receiving technical stimulation, guidance, and leadership from the State health officer in close conjunction with the Technical Cooperation Administration and the Division of International Health of the Public Health Service.

A contract such as that which has been entered into with Massachusetts may be applicable in the case of other States which wish to participate in this program. In some States quite a different pattern might be required. It has been suggested that in certain States it might be desirable to establish a new, separate entity of government under the State health officer. In a number of States specific legislation may be required in order to provide for leave of absence or to encompass service abroad within the framework of State service. The matter needs to be explored on a State-by-State basis because of the variations in legislation and resources.

1950 Census Findings on Health Occupations

About 1,400,000 persons, or 2.5 percent of the total civilian labor force in the United States in April 1950, were employed in a group of 17 health occupations. These estimates are derived from preliminary summarizations of the 1950 Census of Population prepared for the Division of Public Health Methods, Public Health Service. Persons on active duty with the Army, Navy, and Air Force, as well as those unemployed, are not included.

The figures for 1950 as shown in the accompanying table are based on a preliminary summary and are subject to change. Figures for 1940 are from the 1940 Census of Population, adjusted where necessary to conform to the 1950 classification. Final 1950 figures and adjusted 1940 figures for the United States will be published by the Bureau of the Census in the spring of 1953 in the series P-C reports.

Since the census figures differ from those available from other usual sources, it seems important to urge caution in the use and interpretation of the 1950 census findings on health occupations. An attempt is made in the following notes to discuss some of the points to be considered in using the new data.

Physicians

Almost 192,000 persons in the civilian labor force in April 1950 were reported employed as physicians and surgeons in these census tabulations. The increase during the decade 1940-50 was 26,000, or 15.6 percent. During the same period the civilian population showed a net gain of 14.1 percent.

The estimated number of physicians, based upon reports from the American Medical Association, was 205,300 in the spring of 1950. This figure includes 9,900 retired, or not in practice, and 7,500 in the armed forces, leaving 187,900 in active civilian practice. When the 1948

AMA age distribution is applied to the 1950 total and adjustments are made for those retired and in military service, the active civilian physicians fall into the following groups in terms of age at last birthday: 24,200 under 30 years of age, 134,700 from 30 through 64, and 29,000 aged 65 or older as of April 1, 1950.

The census figures are about 8 percent higher than the AMA estimates for the combined age groups under 65 years. The census tabulation shows 26,700 physicians under 30 years of age, an excess of about 2,500 over the AMA. For the age group 30-64, the census enumerated 144,500, about 9,800 more than the AMA. At the younger age the census enumeration may have included some medical students taking clinical training and hence reported as physicians. Obviously, the census count must include, in addition to persons with medical degrees, many thousands in such occupations as chiropractic, dentistry, osteopathy, and veterinary medicine. On the other hand, physicians reporting that they spent all, or a major part of their time, in teaching or administrative work, for example, would not have been classified as physicians in the census.

At the upper end of the age scale the census enumeration is substantially less than the AMA figure. The census tabulation shows 20,800 employed physicians aged 65 or over, about 8,200 fewer than the AMA. Since the census enumerator asked specific questions about work during the week prior to enumeration, many of the older physicians may have reported inactivity at that time although they had not designated themselves as retired in reporting for the American Medical Association Directory.

Dentists

About 75,000 persons were employed as dentists in civilian practice in April 1950, accord-

ing to the 1950 Census of Population. This is an increase of 7.5 percent during the decade 1940-49. Projection on the basis of the preliminary age distribution of employed male dentists indicates that at the time of enumeration about 8,000 of the employed dentists were under 30 years of age, 59,400 were in the age group 30-64, and 7,600 were 65 years of age or older.

Studies published by the American Dental Association indicate that there were about 87,000 living dentists in the spring of 1950. Of this number about 1,600 were in the armed forces. While reliable information on retirement is not available, limited data obtained by the American Dental Association from a surveyed sample of dentists have been published. Application of their findings to the total dentist group suggests that the retired do not number more than a few thousand and that this group, together with those serving with the armed forces, cannot account for all of the difference between the two totals.

Inspection of age distribution data from the two sources indicates that the census count exceeds by a thousand or more the number of dentists under 30 years of age for whom data were

recorded in the ADA files. This excess may reflect the inclusion of some dental students in their clinical training years. For the age span 30-64 years, the count obtained by the Bureau of the Census was several thousand less than the number included in the ADA total even after liberal adjustment is made by subtracting from the ADA total retired dentists and those serving in the armed forces. It seems likely that this under-enumeration may in part explain the excess in physician enumeration discussed previously. While the census total for dentists 65 years of age and older is smaller than the ADA figure for this group, adjustment of the latter by subtracting retired dentists brings the figure into close agreement.

Nursing Occupations

In the field of nursing, four categories of personnel are reported by the Bureau of the Census. These are graduate professional nurses, students of professional nursing, attendants in hospitals and other institutions, and practical nurses, together totaling 810,920 employed in civilian practice in April 1950.

Employed persons in selected health occupations, by sex, for the United States: 1950 and 1940

¹ Data not available. ² Not elsewhere classified.

Source: U. S. Bureau of the Census. Figures for 1950 based on preliminary summarization and subject to revision.

Graduate and student professional nurses are reported separately for the first time, but the census figure for students is far short of the enrollments in the schools of nursing as of January 1, 1950. Census information on the age distribution of those included in the professional nurse count suggests that more than 20,000 individuals reported as professional nurses may actually be students. Adjustments, on this basis and in terms of probable enrollments at the time that the census was taken, give totals of 99,700 professional student nurses and 374,600 employed professional nurses. The combined total for these two categories shows an increase of 34.5 percent over the 1940 census count.

It should be borne in mind that the figure on professional nurses includes all employed graduate nurses whether or not they are currently registered. It seems likely that some nonprofessional nursing personnel also may be included, but the meager data now available from other sources suggest that this error is relatively inconsequential.

Other Health Occupations

The census enumerations of several occupations closely allied to medicine are considerably lower than estimates of active practitioners in 1950 available from the professional associations. Some comparative figures are given below:

	Census	Association
Chiropractors -----	12,807	20,512
Optometrists -----	15,476	19,724
Osteopaths -----	5,146	11,155
Veterinarians -----	13,410	15,305

The figures from the associations include persons in the armed forces and may include some who are retired, inactive, or devoting the major part of their time to other occupations. Adjustment for these factors still shows that the census counts are substantially lower than the estimates from other sources. Further investigation of the census figures will be possible when State tabulations showing detailed characteristics become available in the spring of 1953.

Mrs. Hobby New Federal Security Administrator

Oveta Culp Hobby of Houston, Tex., took office as Federal Security Administrator on January 21, 1953. Fourth Administrator since the Agency's creation in 1939, she will supervise the operations of the Public Health Service, the Social Security Administration (including the Children's Bureau), the Food and Drug Administration, the Office of Education, the Office of Vocational Rehabilitation, Howard University, St. Elizabeths Hospital, the American Printing House for the Blind, and the Columbia Institution for the Deaf.

At the time of her appointment Mrs. Hobby was editor and publisher of the Houston Post and executive director of Station KPRC-AM-FM-TV. Prior to World War II she served as parliamentarian, Texas House of Representatives, and was on the editorial and executive staffs of the Houston Post.

Mrs. Hobby came to Washington in 1941 as chief of the women's interest section of the War Department. When the Women's

Army Auxiliary Corps was created in 1942, she was appointed its director. She also served as director of the Women's Army Corps, with the rank of colonel, from 1943 to 1945.

The Administrator has been active in journalistic affairs, here and abroad, serving on the board of directors of the American Society of Newspaper Editors (1947-50), and as consultant-alternate to the Freedom of Information Conference at Geneva in 1948.

Mrs. Hobby has been a member of the board of directors of the National Conference of Christians and Jews. She has also been a member-at-large of the board of governors of the American National Red Cross. In 1948 she was a consultant to the Bipartisan Commission on Organization of the Executive Branch of the Government, and later became a member of the board of directors of the Citizens Committee for the Hoover Report.

National vice chairman of the 1949 American Cancer Society campaign and a member in 1950 of its national leadership committee and national advisory council, Mrs. Hobby also is a member of the board of directors of the Texas Medical Center.

Seasonal Occurrence of Communicable Diseases

1951 and 1952 Summary

The relatively high incidence of measles and streptococcal sore throat including scarlet fever in the winter and spring months, as compared with summer and fall, is

striking. Meningococcal meningitis and whooping cough also occur more frequently in the winter and spring than in other seasons, but incidence of these dis-

eases is more evenly spread over the entire year than is measles or streptococcal sore throat.

The distribution of two "summer" diseases, typhoid fever and

poliomyelitis, is also different. Typhoid fever is spread throughout the year but has a summer peak; poliomyelitis is mainly concentrated in a few months—July, August, September, and October.

Several of the six diseases occurred in greater numbers in 1952 than in the previous year. This is particularly true for measles and

poliomyelitis. However, in the last half of 1952, incidence of measles was less than that for the same period of 1951. Streptococcal sore throat, including scarlet fever, was reported in larger numbers for each of the 4-week periods of 1952. Incidence of meningococcal meningitis was higher in the winter and spring months of

1952 than it was in 1951; in the summer months of 1952, more typhoid fever occurred than during the same period of the previous year.

This material was prepared by the National Office of Vital Statistics, Public Health Service.

Community-Wide Chest X-Ray Survey

Tuberculosis control rests primarily on the principle of preventing the spread of infection. Now that we have successfully controlled milk-borne infection, our remaining problem centers on finding every human source of infection, every person with active disease, as soon as possible. Supervision and care, the means of preventing further infection and of making the patient non-infectious, can thus be provided at the earliest possible moment.

Since a person with an unknown or hidden case of tuberculosis feels well and looks well, even to the critical observer, the only way to find him is through the screening of apparently healthy population groups—through the screening of entire communities. It is this philosophy which underlies the conduct of every community chest X-ray survey in this country and which has been the basis of radiographic activities of the Public Health Service since 1947.

The role of the Public Health Service in the planning, organizing and conducting of such mass surveys, and the problems that will be met in any community in the planning of a survey are detailed in the eight papers brought together in the publication, "Community-Wide Chest X-ray Survey." Except for the introduction by Dr. James Perkins, managing director of the National Tuberculosis Association, and the article by Dr. R. J. Anderson, chief of the Division of Chronic Disease and Tuberculosis, Public Health Service, all of these papers have appeared in the former Tuberculosis Control Issues of *Public Health Reports*.

In the past 5 years the Public Health Service has assisted 17 communities to conduct mass X-ray surveys. In this time 5,800,000 chest X-ray films (70-mm.) have been taken in a total adult population of some 8,800,000. In his paper, "Ra-

tionale and Results," Dr. Anderson summarizes the results of these 17 surveys in terms of participation, X-ray findings, referrals, and established diagnoses. He concludes with an outline of the average experience from chest X-ray surveys.

The six papers previously published cover the survey pattern, nursing, social work, the diagnostic center, medical profession, and records and reports. Each deals with the planning and organization of various aspects of a survey, the role and responsibilities of the professions in presurvey planning as well as in follow-up services. Step by step procedures are outlined and guides for diagnostic referrals and illustrations of various record and report forms are included.

Cancer Morbidity Series

Numbers 4 and 5 of the cancer morbidity series are concerned with cancer illness among the residents of Denver, Colo., and Pittsburgh, Pa. Patterned like the first three reports, these publications contain charts, tables, and text on the incidence, prevalence, and mortality rates; age, sex, and color differences; stage at diagnosis; survival rates; and hospitalization.

According to the two surveys, the incidence of cancer apparently increased 26 percent in Denver and 31 percent in Pittsburgh during the period 1937-47. In both cities, a much greater increase was noted among males than females. The incidence of cancer of the lung more than doubled for males and almost doubled for females. Each survey showed that the incidence rates for both men and women were highest in 1947 for the following site groups: digestive organs, genital organs, and skin.

Mortality from cancer has been in-

creasing in the United States since 1900, except for white females, for whom the cancer death rate has leveled off since 1936. In Denver, the cancer mortality rate declined 18 percent among females. Between 1939 and 1947 the greatest increase in mortality from cancer of any primary site was from cancer of the lung and bronchus among males.

These surveys give evidence that early diagnosis is closely related to chances for survival. In the Pittsburgh report, this was clearly shown by the 12-month survival rates for cancer of the uterus. When diagnosed in a localized stage, the 12-month survival rate for uterine cancer was 89 percent. When there was regional involvement, 75 percent of the women with uterine cancer survived for 1 year. This percentage dropped to 15 percent when cancer diagnosis was made after metastasis had set in.

Both reports indicate that cancer patients are receiving better medical care. More patients in the two cities received hospital care in 1947 than 10 years previously.

The Practice of Public Health, 1952

Cincinnati, Ohio, May 1, 1873

WE INAUGURATE today the American Public Health Association, the objects of which are "the advancement of sanitary science and the promotion of organizations and measures for the practical application of public hygiene." The field of labor upon which we enter is most inviting to the student of social science and to the philanthropist, for it embraces the highest interests of man and of human society. In its broadest acceptance, sanitary science aims to secure to each individual the most perfect type of the species, immunity from disease, and death from old age, or the natural decay of the structures and functions of the body. The most superficial view of our race discovers the value of a science having such aims, and the momentous task which it proposes to accomplish. On every hand we witness the most prodigal

waste of human life. Inheriting as a birthright health and longevity, we find that man lives but a moiety of his days. Of the children born, what vast percentages never see the anniversary of their birth! What other large percentage dies under 5 years! How few, comparatively, reach the age of 10! At 20 the generation has dwindled to an insignificant minority, and at 33 to 45 it disappears altogether. And even during his short and uncertain life, what physical evils cling like an inheritance to man's body, soul, and estate. . . .

As we contemplate human society in its various stages of development, from that of the savage to the most civilized, from the most ancient to the present time, sickness and death, insanity and imbecility, injustice and violence, everywhere appear as if these were the normal

and related organizations held at Cleveland, Ohio, October 20-24, 1952

Reader's guide on page 204

Nathalie Schmidt, M.S., and Edna Murmann, M.S., from the departments of bacteriology and pathology of the Northwestern University Medical School, Chicago, Ill.

Reporting on results shown by a 2-year study of viral complement fixation tests on serums of hospital and clinic patients, they made the following observations:

Many problems must be solved before these methods become completely reliable. Obstacles included the low yield of positive results, the relative difficulty in interpreting virus tests, and the cost of performing them.

Antigen Control Important

The antigens offered are useful to the average laboratory, but since they are prepared as tissue suspensions, and are not pure virus, they are subject to variation. Therefore, tests in which these antigens are used must be carefully controlled.

Serums from clinic patients symptomatically free of acute viral and rickettsial diseases were first tested routinely with complement fixation techniques against the antigens: lymphogranuloma venereum; psittacosis; influenzas A, B, and FM 1; mumps; eastern equine, western equine, St. Louis, and Japanese B encephalitis; rickettsialpox; spotted fever; Q fever; typhus; rabies; screen spotted fever; and screen typhus.

Of the 275 specimens tested for the lymphogranuloma venereum antigen, 18 gave a positive fixation in a titer of 1:2, and only 1 serum fixed complement in a titer of 1:1,024 with this antigen. Medical histories revealed data showing the relation of the history of illness to the type of antibody found in the specimen taken from each patient. Only two patients gave a history of previous illness (one recent, one past infection).

Hospital Patients Tested

After 9 months' experience with the clinic serums, the tests on serums from acutely ill, febrile hospital pa-

tients were begun. Of the hospital serums, 250 were examined against all the antigens listed above except rabies. Additional serums were examined against lymphogranuloma venereum, Q fever, typhus, spotted fever group antigen, and typhus group antigen. Five serums were examined for rabies antibodies. The first test acute phase specimen was stored in the icebox until the convalescent phase specimen was received, and the two specimens were tested simultaneously against identical antigen dilutions and the hemolytic system on the same day.

Virus Infection Confirmed

Of the results obtained from 435 separated viral complement fixation tests on the serums of hospital patients acutely ill at the time the first specimen was examined, those from 14 patients yielded results interpreted subsequently as giving positive confirmatory evidence of virus infection. Of these, seven reacted to mumps virus antigen, two to the antigen of lymphogranuloma venereum, three to the psittacosis virus antigen, and two to the antigens of influenza viruses. Attention was directed to a case of meningitis re-

Tests for viral diseases

ported as due to the virus of lymphogranuloma venereum.

In both the clinic and hospital groups positive titer responses to lymphogranuloma venereum, psittacosis, the influenza, and mumps antigens were far greater than for the other antigens represented in the study. The only instances in which positive serologic diagnoses were made were for this same series of diseases.

No serologic diagnosis of neuroarthropod-borne encephalitis was made, nor was a diagnosis forthcoming for any disease caused by the classical rickettsiae.

Army Medical Laboratory Tests Influenza Virus

Studies at the First Army Area Medical Laboratory in New York City indicate that the same serums tested for viral influenza infections suggest greater sensitivity of antibody rise by complement fixation than by hemagglutination inhibition.

The findings were based on results of examination by complement fixation and hemagglutination inhibition of 761 pairs of acute and convalescent serums against the 1940 influenza virus strain B (Lee), reported

by Lt. Col. Andrew Fodor, MSC, and Lt. Col. James L. Hansen, MC.

Obstacles Encountered

Describing the procedures and materials used in their investigation, they reported that an obstacle encountered during the study was the development of erythrocyte agglutinating factors in the serums submitted for examination. These agglutinins were detected in virus-free controls and were usually associated with bacterial and fungal growths which developed in spite of refrigerated storage of the serums. Titrations were rendered unreadable particularly when these agglutination titers extended beyond the virus agglutination-inhibiting capacity of the serum. The difference in sensitivity may be based on the measurement of different antigenic factors, the investigators felt.

Further studies to establish the significance of these observations with a B virus strain isolated during this period are in progress, the officers said.

Texas "Flu" Epidemic Virus Identified

Identification of influenza type B in the 1945 epidemic in Texas and type A' during the 1947 and 1951 influenza outbreaks follows the observations for other parts of the country. The report of the laboratory tests in Texas was made by J. V. Irons, Sc.D., director of laboratories, and Thelma D. Sullivan, M.S., and Margaret N. Norris, B.S., virologists of the Texas State Department of Health.

The laboratory found serologic tests more rewarding in the identification of influenza types than attempts to isolate the etiological agent. Hemagglutination inhibition tests were made on paired serums from typical cases. However, A' virus was recovered from throat washings of two typical cases during the 1951 epidemic.

Tests for viral diseases—Continued

Disease	Recommended tests	Material needed
Mumps----- Viral keratoconjunctivitis and conjunctivitis.	1. Complement fixation-- 1. Neutralization with epidemic keratoconjunctivitis and Newcastle disease virus. 2. Virus isolation-----	Serum. Serum. ¹ Conjunctival washings. ²
Inclusion blennorrhoea. Stomatitis or generalized vesicular eruptions.	1. Microscopic examination. 1. Microscopic examination for inclusion bodies. 2. Isolation of virus-----	Conjunctival scraping. Scraping or biopsy. Vesicular fluid or mouth swab. ³
Lymphogranuloma venereum.	3. Neutralization----- 1. Complement fixation--	Serum. ¹ Serum. ¹
Typhus-----	1. Complement fixation-- 2. Agglutination with epidemic and murine rickettsiae. 3. Weil-Felix. ³	Serum. ¹

¹ Usually two serums are needed; one taken early in the acute phase of illness, the other 12 to 16 days after onset; may be mailed in liquid condition.

² Should be frozen with dry ice and delivered frozen.

³ Useful in presumptive diagnosis of rickettsial infections and helpful in differentiating between Rocky Mountain spotted fever and rickettsialpox.

—From paper by M. Michael Sigel, Ph.D., Philadelphia.

A Century of Progress in Sanitary Engineering

No longer is the sanitary engineer considered merely a civil engineer specializing in sanitation. With the increased recognition of environment as an important factor influencing health, and the changes for the better that the sanitary engineer can achieve in that environment, his role has expanded to the point where he now is constantly attaining greater professional maturity, according to the speakers addressing a joint session of the APHA engineering section and the Ohio Association of Sanitarians.

Public Health "Giants" Of 1890-1910 Acclaimed

Prior to 1890, practically nothing of the actual scientific fundamentals of sanitary science was known, while by 1910, the basic principles of that science had been well and truly established, declared C.-E. A. Winslow, Dr.P.H., editor of the *American Journal of Public Health* and professor emeritus of public health at Yale University.

For more than half that period. Dr. Winslow was a student and instructor at the Massachusetts Institute of Technology. In retrospect, he views those decades in Boston as "one of the most remarkable periods in the history of public health." and he feels that the men he knew had "attributes of real greatness."

"The notable advances of the time were, of course, made possible by the application of the new science of bacteriology," he said. "They were actually effectuated through a peculiarly intimate relationship between the Massachusetts State Board of

Health and a remarkable group of pioneers on the Technology faculty."

Faculty and Officials

"William T. Sedgwick, head of the department of biology, was operating what was, in essence, the first school of public health in the world," Dr. Winslow declared. "Thomas M. Drown was establishing the basis of sanitary chemistry. . . . In 1880, the Lawrence experiment station was set up under the guidance of Sedgwick and Drown. In the 16-foot cypress tanks on the banks of the Merrimac River, the basic principles of the oxidative purification of sewage were first developed; and the Lawrence city filters, in 1883, provided the first scientifically controlled demonstration of water purification. Sedgwick and J. H. Batchelder initiated work on milk bacteriology and began the long battle for pasteurization in 1892. . . . In the Annual Report of the State Board of Health for 1892, Sedgwick presented studies on typhoid fever epidemics . . . which were classics in the field."

On the public health side of this relationship between a State and a university, Dr. Winslow noted Henry P. Wolecott, president of the board of health; Charles Harrington, secretary of the board; and Samuel H. Durgin, health officer of Boston. He named Hiram F. Mills as perhaps the greatest figure in engineering.

Among his more intimate associates, he acclaimed George W. Fuller, who "was responsible for notable pioneer studies of water purification at Louisville and Cincinnati" and who "more than any other one person was responsible for the development of the 'Standard Methods of Water Analysis' of the APHA"; Allen Hazen, who "assisted Hiram F. Mills in preparing the plans for the

Lawrence filter . . . developed the procedures for the mechanical analysis of sand, in use to this day . . . and planned the sewage disposal system for the Chicago Exposition in 1893"; and George Whipple, a member of the triumvirate, with Sedgwick and Milton J. Rosenau, which established the Harvard-Technology School for Health Officers in 1913, and author of "Microscopy of Drinking Water," still the standard work in that field.

Epidemiologist and Teacher

But the "inspiring center of the new movement was William Thompson Sedgwick," Dr. Winslow stated. Not a laboratory investigator, he nevertheless fully realized the importance of basic scientific study. "It was primarily due to his leadership that the laboratories at MIT pioneered in the application of the new tools of science to water treatment and sewage treatment, to the bacteriology of water and milk, of ice and air and food," he noted.

"In epidemiology, Sedgwick played a more direct and personal role . . . was indeed the first scientific American epidemiologist . . . the first to study the phenomena of epidemic prevalence by quantitative methods." He also, according to Dr. Winslow, was "a pioneer in the task of interpreting the possibilities of the budding science of public health to the public . . . a crusader in a new and inspiring cause."

"Most important of all, Sedgwick was an inspired and inspiring teacher," he said. The qualities which made him so, Dr. Winslow explained, were, first, "an almost passionate interest in exactitude as to words and the realities for which words stand and the relationships of words and facts in a universe which was always a connected and significant whole," and second, "his automatic assumption that the basic aim of the individual life was service to the common cause of human progress."

Dr. Winslow concluded that Sedgwick may truly be called a "giant." "I think, however, that he would

have wished me to point out that he did not create his attitude toward life out of whole cloth," he added. "Giants stand on the shoulders of giants. Sedgwick was the inheritor of a great tradition—the tradition of the late Victorians—. . . to which he gave new life and which may still lead us out of the confusions of a changing world . . ."

Claims Sanitary Engineering Deserves New Status

The ever broadening scope of sanitary engineering activities demands a break from the traditional concept of sanitary engineering as merely a branch of civil engineering, declared Earle B. Phelps, B.S., and John E. Kiker, Jr., M.C.E., lecturer and professor, respectively, of the University of Florida's College of Engineering.

"Hippocrates, Pasteur, Chadwick, Shattuck, Sedgwick, and all the others whom we claim as illustrious ancestors in sanitary science are distinguished by their innovations and departures from the traditional," they said.

Modern sanitary engineering began with the discoveries of the water-borne characteristics of enteric diseases which, in turn, led to studies of possible preventive measures, they continued. But in recent years the responsibilities of the sanitary engineer have so expanded that he now must cope also with problems of stream and atmospheric pollution, milk and shellfish sanitation, industrial and school hygiene (including ventilation and lighting), rodent control, restaurant sanitation, and many others.

The term "public health engineering" was coined to emphasize this broadened concept of sanitary engineering as a field embracing all aspects of environmental sanitation in contrast to the earlier, more narrow concept, they said.

They concluded that training in basic engineering subjects obviously is essential, but if sanitary engineer-

ing is to achieve maturity as a unified science such courses as bacteriology, parasitology, and (quantitative analysis) chemistry also must be included in undergraduate curriculums.

Environmental Conditions Cause Fifth of Deaths

An estimated one-fifth of all deaths in the world are due to environmental conditions such as unsanitary water supplies, and lack of effective control of flies and insects, of cholera, and of bilharziasis, stated Herbert M. Bosch, M.P.H., professor of public health, Engineering School of Public Health, University of Minnesota.

"The rise of the United States to a position of world leadership has made it mandatory that Americans think of global health problems. . . . World leadership has brought with it a responsibility for world health," he asserted.

The solution of the sanitation problems in any country will be one which fully utilizes local labor and material and which does not deviate too widely from the local cultural patterns. American sanitation methods may not be satisfactory in a foreign country, he pointed out.

Safe Water a Problem

For example, he noted, it would be economically impossible to supply enough hand pumps and well casing for all the small villages in Africa and Asia. Supplying safe water for such small villages is thus still a problem. In many parts of the world, he continued, human excreta is used for fertilizer, and no method for such use has been developed which satisfies both the sanitary engineer and the peasant.

The continued success of sanitation programs in any country depends on a core of nationals competent in public health engineering, he said. Urging establishment of training centers in other countries, Mr. Bosch felt more benefit would

be gained by giving training in regions nearer environmental conditions native to the trainees.

On the question of whether service in foreign countries is a satisfying professional experience, Mr. Bosch said: "Many . . . derive satisfaction from being able to do work which has such measurable results. Those who have been most successful are men who are willing to learn from a country as well as to teach, who like to work with people, who do not have a feeling of superiority, and who attempt to understand and appreciate the culture of the country in which they are working."

To Solve Modern Problems Teamwork Is Required

Engineers in public health cannot rest on the laurels of their past performances, since tremendous responsibilities lie ahead in many of the underprivileged areas of the world and an untold amount of work confronts them in many parts of this country, asserted Rolf Eliassen, Sc.D., professor of sanitary engineering at Massachusetts Institute of Technology, in a talk on environmental health for the next century.

Throughout his presentation Dr. Eliassen called for "unsurpassed" cooperation between engineers and other scientists in public health. Almost every modern problem, he said, calls for teamwork with a different set of public health scientists.

Waste Disposal

Refuse disposal is a major engineering problem in most cities. It has been estimated that 8,000 communities need modern refuse disposal facilities in this country alone, not to mention those communities which need modernization of sanitary equipment and methods, he reported.

Sewage and industrial waste treatment plants should be improved. We need faster acting, smaller, and cheaper treatment plants in order to promote water pollution abatement, he said.

Agriculturalists all over the world are clamoring for more organic fertilizers and limus material to build the soil and maintain high productivity, Dr. Eliassen commented.

More economical and more readily applied methods of insect control are needed, he noted.

Food Sanitation

Food sanitation, although quite well developed, "stares us in the face" when reliable sources estimate that there are about 1,000,000 food poisoning cases a year, he said. Although dishwashing has been advanced by engineering, the methods of desolling and storage of dishes could be improved to keep the dishes sanitary, he noted as an example.

Housing

The hygiene of housing is a tremendous task facing the profession. Home accidents, a major source of disability and mortality, must be fought as well. Leadership for the enactment and enforcement of rational housing standards, for the construction of new housing, for rehabilitation of substandard housing, and for adequate maintenance of approved housing must be furnished, according to Dr. Eliassen.

Air pollution is a problem demanding much research by allied scientists, he reported. Problems now unknown will also face the profession in the future.

Simple and inexpensive means of securing good water for the underprivileged areas of the world should be developed, Dr. Eliassen concluded.

Urges Engineers Study Environmental Stress

Since the primary concern of sanitary engineering is the control of environmental stresses upon man to maintain health and well-being, its principal objective, in the opinion of Theodore Hatch, M.S., is to anticipate and prevent excessive environ-

mental problems rather than to correct bad situations after they have developed.

Mr. Hatch, who is with the University of Pittsburgh's Graduate School of Public Health and the Mellon Institute's Industrial Hygiene Foundation, said that sanitary engineers must develop a deep understanding of man-environmental relationships—a knowledge of human response to environmental stress which can be translated into engineering terms and wedded with basic engineering knowledge and skills. He felt that such knowledge permits human factors to be dealt with in engineering analysis and design on a par with physical laws which govern ordinary engineering practice.

But human behavior is complex and cannot be reduced completely to equations, Mr. Hatch continued. The sanitary engineer must distinguish between emotionally evalu-

ated and descriptively handled behavior aspects and the man-environmental relationships which meet engineering criteria. Nor can he work independently, said Mr. Hatch. The translation of laws of human response to environmental stress into engineering terms for regular use in analysis and design requires the participation of biological and medical scientists as well as sanitary engineers, and the field is therefore an overlapping one that must be developed and shared equally by the two groups.

There is still a need for engineering skills in the control of infectious diseases, and the need will continue until adequate sanitation is provided for all the people, he said.

But "the need in new areas for joint research and close collaboration of engineers and other physical scientists with biological and medical scientists is even greater," he emphasized.

Epidemiological and Control Aspects of Anthrax

The 1951-52 outbreaks of anthrax in animals were reviewed in epidemiological and preventive terms during sessions of the Conference of Public Health Veterinarians and the APHA engineering, epidemiology, food and nutrition, and laboratory sections. Reports were presented on bonemeal as the source of infection in Ohio swine, on the control problems, and on economic effects. An increase of human anthrax of industrial origin was also noted.

CDC Veterinarian Outlines Anthrax Control Measures

Numerous outbreaks of animal anthrax in the United States during 1951-52 were traced to contaminated bonemeal, said James H. Steele, D.V.M., M.P.H., chief, veterinary public health services, Communicable Disease Center, Public Health Service.

Most cases occurred in Ohio, Indiana, and other midwestern States, he noted. Michigan reported its first case since 1916. None of the States were considered anthrax enzootic areas, he said.

Anthrax was prevalent in cattle, horses, sheep, and mink, but most outbreaks were among swine. Nearly all the diseased hogs were pregnant or nursing sows on a high protein-calcium ration, he said.

No human cases were attributed to any of the swine outbreaks, Dr. Steele stated.

Control Measures

The U. S. Department of Agriculture now prohibits importation of

raw bonemeal. It also requires that any bonemeal brought into the country be sterilized at 250° F. under 20 pounds' pressure. Many States have similar regulations, Dr. Steele reported. In the Ohio outbreak, he observed, penicillin or other antibiotics were preferred to immunizing agents in controlling anthrax in swine. But in treating cattle, penicillin is not recommended in place of vaccination because relapses have followed injection, he said. He pointed out that aureomycin and terramycin were successful, however.

Even though anthrax is not readily transmitted to man, control measures for handling milk from infected premises, for processing meat animals from known infected farms, and for preventing occupational disease among animal handlers are needed to remove any threat to public health, Dr. Steele stated.

Prevention of occupational anthrax can best be answered by health education, he concluded. Meat animals from infected farms should be processed in abattoirs or packing plants under Federal or local inspection services, he said.

Quarantine of the premises does not always answer the problem of handling milk from a farm where anthrax has infected a milking herd or other animals, he said. Unduly stringent quarantine regulations may discourage reporting of the disease and cause economic loss for the dairyman, he warned.

"I have had the opportunity to see some sizable nuisance problems develop when the milk from 500 or 600 cows is dumped on a farm in a warm climate," he observed.

Proposed Dairy Control

Dr. Steele read proposed Public Health Service recommendations for controlling anthrax in milk herds.

Presented a week in advance of discussion at the Louisville convention of the U. S. Livestock Sanitary Association, the rules were drafted with assistance from the U. S. Bureau of Animal Industry, the Federal Food and Drug Administration, the Federal Civil Defense Administration, the American Veterinary Medical Association, and the U. S. Livestock Sanitary Association. They stipulated that:

No milk be sold from suspected animals until a licensed veterinarian declares them anthrax-free; animals with temperatures of 103° F. or other signs of the disease be isolated from the milking herd; milking utensils be sterilized for 30 minutes after exposure to contamination; and dairy barns be thoroughly cleansed by washing and treatment with a 5-percent lye solution for 2 hours after discovery of the disease.

The regulations call for reporting of cases to the local health officer and veterinarian, control of the disease by the local health department and State livestock sanitary officials, and close cooperation between the milk and livestock disease control authorities.

Economic Losses Result From Anthrax Outbreak

The 1952 outbreak of anthrax in Ohio affected the economics of many phases of the Ohio livestock industry, according to the report presented by James R. Hay, D.V.M., chief of the division of animal industry, Ohio Department of Agriculture.

Although the loss incurred by deaths of affected animals (brood sows) was not significantly high, averaging 1½ animals on each of the 287 affected farms, the outbreak had detrimental effects upon such economic factors as swine feeding practices, the sale of swine, interstate movements of all livestock, and even the sale of milk, he said.

The major loss suffered by the swine industry resulted from the

changes in feeding practices, Dr. Hay believes. The knowledge that contaminated raw bonemeal had caused the outbreak led many breeders and feeders to discontinue the use of mineral feeds, despite the fact that the manufacturer of the contaminated product had recalled all unused portions.

Many breeders also ceased purchasing commercial supplements because they contained bonemeal or animal protein, he reported. Vegetable proteins were frequently substituted for animal protein. Moreover, in some instances feeders wasted money by increasing the antibiotic in the feeds over the known "growth factor" level.

Many packers and processors refused to purchase swine from any farm located in a county where anthrax had been diagnosed, Dr. Hay also pointed out. This in turn precipitated fear in the minds of some producers, who sold their swine for slaughter before they had reached ideal market weight.

Further economic losses undoubtedly resulted from outbreaks of hog cholera during the summer of 1952, some of which may be attributed to the fact that farmers did not have their swine vaccinated during the anthrax period, Dr. Hay indicated.

The occurrence of anthrax also affected milk producers since in some

instances milk from dairy farms having affected swine was rejected. Some local sanitary boards refused to permit the flow of milk into regular channels from quarantined farms regardless of sanitation, management, and isolation practices.

However, the outbreak stimulated a desire for an efficient state-wide meat inspection program. "The use of sterilized used feed bags will have a far-reaching effect in minimizing the spread of many livestock diseases," he concluded. "The new Federal regulations governing international shipment of animal feedstuffs will likewise provide security."

Epidemiology of Anthrax In the United States

Human anthrax of industrial origin has increased in the United States during the past decade, especially in the New England and Middle Atlantic States, Arthur H. Wolff, D.V.M., of the radiological health training section, Environmental Health Center, Cincinnati, reported.

The infective agents, he said, are imported goat hair, goat skins, and carpet wool from Asia, North Africa, and possibly southern Europe. Although there has been an increase in reported cases in man, the annual

average has been less than 70 cases during the past 11 years, 75 percent of which were industrial in nature and were attributed to animal materials. Since the introduction of penicillin therapy, few or no deaths from cutaneous anthrax have been reported when diagnosis and treatment were reasonably early.

Worst Anthrax Outbreak From Imported Bonemeal

Anthrax spores imported in 1952 in raw bonemeal were the cause for the most severe anthrax outbreak in swine on record in Ohio, according to H. G. Geyer, D.V.M., and H. E. Goldstein, D.V.M., former chief and field investigator, respectively, of the division of animal industry, State Department of Agriculture.

The sporadic outbreaks of 1910, 1923, and 1951 had involved only one or two farms in the State, but the 1952 epidemic spread into many counties, they reported. However, there was a loss of only 384 hogs from 264 farms, and the disease did not appear to spread to other animals.

Prompt reporting by veterinarians, adequate quarantine, and early administration of penicillin and anti-anthrax serum were the control measures which brought success to the program, they stated.

public health

in transition

This past half century has witnessed an evolution in traditional public health activities. The task of basic sanitation continues, but takes on new dimensions. We move against communicable disease not in terms of containment, but of prevention—in some cases, of eradication. Today's laboratory is essential to epidemiology, diagnosis, treatment—and itself

breaks new paths in research. In shaping our course of action we rely upon data acquired through the nation-wide cooperative system of vital records and health statistics—another product of these 50 fruitful years.

Meantime, new concepts, new programs, have come into being. Even a partial listing of areas of public health practice of common acceptance today would include . . .

Community health education . . . professional training . . . tuberculosis and venereal disease control . . . school health . . . nutrition . . . malaria and insect vector control . . . public health nursing . . . water pollution control . . . occupational health . . . diabetes

control . . . mental hygiene . . . cancer services . . . epidemiological, administrative, social, clinical research . . . medical care . . . dental programs . . . maternal and child health services . . . housing and health . . . radon control . . . radiation protection . . . heart disease control . . . multiple screening . . . hospital planning and construction . . . rehabilitation . . . blood programs . . . accident prevention . . . civil defense.

Today's public health programs have emerged in response to recognized needs. Action has come with advances in the biological, physical, and social sciences. The pictures following highlight some of these current and developing fields of local, State, and Federal health services. ▶

Policies for the Promotion Of Healthful School Life

A joint session of the APHA sections on maternal and child health, public health education, public health nursing, school health, and health officers with the American School Health Association sought to bring up to date developments in the field of school health policies. Among topics discussed in light of the forthcoming revision of the standard reference under this title were: promoting healthful living in schools, health and safety education, services for health protection and improvement, health aspects of physical education, and school responsibilities for the education and care of handicapped children.

Outlines Major Revision In School Health Policy

Redirecting school health education would clarify current school health policies, Helen M. Starr, Ph.D., director of health, physical education, and recreation for Minneapolis Public Schools, declared.

"We are not carrying out the recommendations of the present report," she said, referring to current APHA policy carry-over to present health education. Many schools are teaching health rather than helping boys and girls live healthfully through sound instruction, she said.

"Why not tie in the aspects of health service and healthful school

This album material (and last month's) is adapted from the Public Health Service exhibit at the 1952 APHA meeting.

living with the program of health and safety education in revising current policies?" Dr. Starr asked. Listing the services and living activities which are a regular part of the health curriculum would contribute to program integration, she said.

Dr. Starr appealed for major policy restatements on the objective of health education, coordination of the program and integration of its various parts, organization of the health course, introduction of a health program into the schools, and more specific standards of guiding the program.

Instruction Objectives

Primarily, a policy revision should state the understanding, attitudes, and skills to be achieved by health education in a complete curriculum, Dr. Starr said. Its formulation would serve to determine the content of health courses, the needed school and community health services, and later to evaluate the effectiveness of health teaching, she

believes. As examples of understanding, she listed:

Good health is a state of complete physical, mental, emotional, and social well-being, not merely the absence of disease. Individuals differ in their rate of growth and in their capacities. Their acceptance of this difference is necessary to good mental health. Complete medical, dental, and psychiatric services are available for improving health.

Desirable attitudes, she said, are appreciation of preventive medicine and public health education programs, cooperation in maintaining high health standards in the home, school, and community, and acceptance of one's strengths and limitations.

Suggested health teaching areas to be included at each level of the school experience are these, she said: human growth and development; health maintenance and improvement; dental health; nutrition, rest, relaxation, and exercise; personal appearance, mental health, and personality development; home and family living; alcohol; narcotics and drugs; safety education including civil defense and disaster education; and public health.

"The health course should carry the same recognition in regard to credit and requirements as other basic courses," she said.

Capacities Only Limit For Handicapped Child

Handicapped children should be helped to participate in activities with normal children to the extent of their capabilities, declared Arthur J. Lesser, M.D., director of the Division of Health Services of the Children's Bureau, Federal Security Agency.

The physical, intellectual, social, and emotional needs of crippled children are basically the same as those of other children, he said. Although they may find the problems of growing up accentuated because of their handicaps, they can best face the rest of the world if they learn to do so from early childhood.

"With our help," he continued, "they can develop to the extent of their physical and mental capacities and most of them can become independent contributing members of society." He said this requires a well-planned community health and education program that includes case finding, diagnostic and treatment services, social services, education (including special education), and vocational counseling.

For children too handicapped for education in regular classes, Dr. Lesser continued, special classes are becoming increasingly common. However, too few schools now have such programs since provision for educating orthopedically handicapped children, for example, should include: transportation by bus with an attendant or by taxi, ramps and elevators, close medical supervision by pediatricians and orthopedists, physical and occupational therapy, hot lunches, specially trained teachers and other personnel, and rest facilities.

Problems Differ

The best type of school situation for the handicapped child must be determined by each individual's requirements, Dr. Lesser stressed. Some children may be so handicapped that they are unable to attend regular or special classes and there-

fore must be educated in special schools, hospitals or their homes. Also, he said, orthopedically handicapped children may present different educational problems than, for instance, those with cerebral palsy, epilepsy, or hearing difficulties.

Some handicapped children, particularly epileptics, are excluded from or are unhappy in school because of social stigmas attached to their disorders, said the doctor. He felt that they should not be excluded and that the other children's reaction toward the handicapped child will mainly reflect the attitude of the teacher.

In fact, he concluded, handicapped children should begin their formal education much earlier than normal children. When children have serious neuromuscular or hearing handicaps, he said, the preschool years become particularly important for their growth and development. He felt that although only a start has been made, the nursery school movement for the handicapped gradually is becoming more influential.

Schools Should Blueprint Plans for Health Action

Formulation of a well-publicized written plan assuring uniformity of intelligent action in emergencies, protection of children against neglect, and prevention of communicable disease will act to reduce unjustified criticism of schools, Carl A. Wilzbach, M.D., commissioner of health, Cincinnati, said in discussing school health protection and improvement.

School personnel, with aid of local medical societies, should draw up such blueprints to solve problems such as the safe transfer of responsibility to parents or other persons when emergencies occur and the treatment of children injured or taken ill when parents cannot be reached, he said.

Accidents and illnesses are bound to occur in schools, and a program of action including teacher training in

first aid procedures will prevent further injury and assure the family that needed medical services are obtained as promptly as possible.

Dr. Wilzbach outlined the need for keeping files of names, home and business addresses and telephone numbers of parents and neighbors, and a current active system of accident reporting. He also stated that schools have a direct responsibility in the prevention and control of communicable disease, and should establish cordial working relationships between schools and health departments and local medical societies. He advocated the services of a medical adviser for every school.

During the school years, Dr. Wilzbach urged that students should have a minimum of four medical examinations; one at the time of entrance, one in the intermediate grades, one at the beginning of adolescence, and one before leaving school. He also stressed the importance of referral of examinations to doctors selected by the students' parents.

The speaker felt that community resources should be made available to meet the health needs of school children, particularly specialized medical consultation of a diagnostic nature.

Broader Health Course Advised for Teachers

Use of a physician's services in a school's physical education program and better preparation in the biological sciences for physical education teachers were stressed by Herbert F. Walker, Ph.D., professor of health education, Columbia University Teachers College, in a discussion of practices and policies that create a healthful climate for athletics and physical activities.

The general requirement that all school pupils take part in the physical education program presents potential health problems, he said. Individuals vary widely in their capacity to perform muscular ac-

The Scope and Characteristics Of Occupational Health

The scope and characteristics of occupational health programs are undergoing modifications in keeping with new industrial processes and changing concepts of industrial-community relations, health officers and industrial hygienists were told at the APHA.

Air Pollution, Isotopes Concern Health Units

Air pollution and the use of many new chemicals and radioactive isotopes in industry and medicine are among the challenging problems facing the local health officer in the often neglected field of industrial hygiene, according to Huntington Williams, M.D., commissioner of health of Baltimore.

Dr. Williams traced the 30-year history of Baltimore's efforts in the field. Revision of the State's workmen's compensation law gave the State and city health departments responsibility for controlling and

preventing occupational diseases and permitted them to adopt regulations. The cooperation between the health and labor departments, and later, the city buildings engineer, produced good results.

Confidence in the program developed, and management and labor began to seek guidance on health protection from the department, he said. A senior medical supervisor for occupational diseases was appointed. Close working relationships with official and civic groups were found necessary for an effective program, he said.

Lead Poisoning

Lead poisoning was found to be an occupational hazard in Baltimore and a special blood-lead laboratory was set up to help pin down this disease in and out of industry. Children of teething age who had chewed on window sills were found to have become severely ill from the lead paint used at one time. The blood-lead laboratory helped in diagnosing this disorder, he said.

Another community service cited by Dr. Williams was the tracing of

tivity. A physician is needed to classify the pupils according to physical fitness.

In the interest of pupil adjustment, Dr. Walker said, it is usually recommended that the pupil be kept on the class roster and given academic credit for the things he can do.

In addition to the customary medical services in interscholastic athletics, Dr. Walker suggested a closer identification of the medical staff with administrative decisions that relate to health, such as the length of the playing season or the practice sessions.

Dr. Walker found the present requirement of teacher certification for athletic coaches a far cry from the practice of accepting volunteered services of a former athlete to coach the school team. He also indicated progress in specifying course work.

But additional emphasis, he stated, could well be placed on public health problems, human growth and development, and health counseling in the preparation of the physical education teacher.

"School Health Policies," Revision in Preparation

"Suggested School Health Policies" is to be revised for the second time, Charles C. Wilson, M.D., professor of education and public health, department of public health, Yale University, announced.

This booklet, prepared by a committee of the maternal and child health section with advice from other APHA sections and several national organizations concerned with school health, was first published in 1940 and revised in 1945, Dr. Wilson noted. It is designed "to provide a clear, comprehensive, printed statement of the consensus of well-informed professional opinion concerning many specific school policies which directly or indirectly affect the health of children and adults," he said.

Community Benefits From Industrial Medicine

Industrial medicine has achieved significant results in prevention and control of occupational injuries and diseases and, through cooperation with community health services, has contributed to the control and prevention of venereal diseases, pulmonary tuberculosis, and other infectious diseases, said C. D. Selby, M.D., resident lecturer in industrial hygiene, University of Michigan School of Public Health.

The responsibilities of both industrial medical services and community health programs are essentially those of private physicians, he asserted—the protection and preservation of community health. He felt, however, that because of their positions in industry and the specialized knowledge they possess, industrial physicians acquire additional obligations of mass "health maintenance."

The procedures of industrial health which offer the best opportunities for cooperation with community health programs, Dr. Selby continued, are: (1) examinations of applicants for employment; (2) employee examinations for health maintenance; (3) case finding; (4) consultation and advice to employees on their health problems; (5) health education; (6) industrial hygiene and sanitation; and (7) biostatistical studies of both occupational and nonoccupational employee disabilities.

Examinations Are Multiphasic

As an example of the opportunities these "tools" offer for cooperation with community health programs, Dr. Selby cited the examinations which assist greatly in multiphasic screen testing. Employee examinations are multiphasic and much more

complete and clinically sound than most community testing programs.

The industrial physician is interested in virtually the same health problems as the health officer, Dr. Selby continued, since both influence the quantity and quality of employees' work. He felt that they should cooperate especially in problems of accidents, home environment, occupational hygiene, chronic diseases and constitutional conditions of the aged, referral of patients to needed specialists and hospitals, rehabilitation of the crippled and disabled, and mental hygiene.

Periodic Health Survey Benefits Discussed

Periodic health examinations provided by many corporations for their employees should not be in competition with diagnostic clinics nor the practice of medicine in the community, said W. Leigh Cook, Jr., M.D., assistant professor of medicine, University of Pittsburgh.

He pointed out that corporations and groups of industrial workers have undertaken this preventive activity because a large number of people fail to seek a regular check-up.

In this type of examination the person is being screened for telltale evidence of lack of good general health, and, said Dr. Cook, he should not expect exhaustive diagnostic procedures.

Advantages of Check-Ups

One of the advantages to be gained from a periodic examination, according to Dr. Cook, is that the patient actually presents himself to a physician for an examination. The examination will also make the patient realize that his health is important not only to himself but to the corporation, he said, pointing out that a healthy employee is a good employee, while a sick employee is likely to make mistakes that cost the corporation needless losses.

Dr. Cook listed as a third advantage the discovery of infectious or degenerative disease processes, such as diabetes, hypertension, progressive arteriosclerosis, tuberculosis, anemia, leukemia, and tumors, which have not been noted by the patient. The patient with physical disabilities will be reassured concerning management of his problem, he said.

The last advantage outlined by Dr. Cook was the maintenance of individual records over a long period of time. These base-line laboratory and objective findings are important in evaluating a sudden illness or symptoms that might stem from a particular organ which has shown an abnormality in the periodic examination, he explained.

What To Include

Dr. Cook expressed the belief that adequate information for periodic survey purposes can be obtained from a careful medical history, functional inquiry, a complete physical examination, a blood count with differential, a complete urinalysis, an X-ray of the chest or an adequate fluoroscopic examination, and an electrocardiogram. He advised that records of these examinations be made available to family physicians. Those who have specific complaints should not be diagnosed in a periodic survey, but should go to their own physicians or diagnostic clinic, he said.

Basic Information Needed To Control Radiation

Without base-line information as to whether there are any appreciable number of people exposed to radiation in biologically significant amounts and how much of an increase in radiation would be required to reach such a level, it is difficult for public health departments to know what course to chart in the problems posed by the possibility of long-term radiation exposure, in the opinion of Duncan A.

Holaday, M.A., chief of the Salt Lake City radiation unit of the Division of Occupational Health, Public Health Service.

Questions for Health Officers

He said health officials should concern themselves with challenging questions such as these:

Just what are the radiation sources in your area and where are they located? Are all the X-ray machines situated in hospitals, doctors' and dentists' offices, and industrial establishments? Is this equipment properly safeguarded and by whom? Is any effort made to measure and record the exposure of the technicians who control this equipment? How much of the 600 gm. of radium used to make luminous paint in the last 10 years has come to rest in your area? What levels of radon are normally present in your area and how do atmospheric conditions affect these concentrations? How is the radium content of water affected by treatment schedules?

Geneticists have spoken out in plain words on the danger of receiving a lifetime dose of from 30 r to 80 r, and their opinions should be given more than passing attention, Mr. Holaday warned.

Geneticists report that such a dose would double the spontaneous mutation rate, Mr. Holaday explained.

Radiation is known to induce inheritable changes or mutations in animals, he continued, adding that humans are probably more sensitive to radiation than most animals. In contrast to most radiation effects which indicate that small radiation doses are not directly additive, genetic studies show that fractional irradiation doses have a cumulative mutagenic effect.

Sources of Radiation

Mr. Holaday presented data on small doses of radiation and listed the sources of radiation to which an average person may be exposed. These, he said, are:

Cosmic ray background. Exposure is estimated to be at least 0.1 r per year. This is inescapable.

Small amounts of radioactive elements which are distributed in water, soil, and air. If these were evenly distributed, which they are not, throughout the skeleton, they would deliver a radiation dose of about 0.8 rep per year to the bone.

Natural radioactive materials used in industry. Workers in carefully monitored installations receive total exposures far less than 15.6 r per year, the maximum permissible dose.

Doses from common diagnostic procedures used by radiologists. Some of these quantities are: chest, large X-ray, 0.1 r; chest, photofluoroscope, 1.0 r; pregnancy, lateral, 9 r; gastrointestinal series, 4 r to 50 r; average dental film, 5 r; fluoroscopic examination, 10-20 r/min.

Instances of the use of radiation for such trivial purposes as the removal of superfluous hair.

Customer Can Rely on Chemical Suppliers

What are the chemical supplier's responsibilities to his customer? Edgar M. Adams, Ph.D., assistant director of the biochemical research department, Dow Chemical Company, Midland, Mich., answered that the supplier can be expected to inform the customer sufficiently

about the health hazards of his product.

Accordingly, he said, the supplier must obtain information on harmful properties of chemicals, advise customers of these properties and of precautions, and assure that the uses he recommends are appropriate. Only indirectly can the supplier influence the operations of his customer.

Types of Hazards

"The likelihood that a given product will cause harm of any sort will depend upon chemical and physical properties, toxicity, use of the product, and the type and number of customers," Dr. Adams pointed out. "A substance used as a chemical intermediate cannot offer a hazard even approaching that presented by substances going into such products as cosmetics, fabrics, and pesticides. Each individual use must be evaluated on the basis of the nature and intensity of the exposures which can occur. Entirely apart from the likelihood of difficulty, the seller of chemicals will assume a varying liability for the safe use of his products depending upon the type of product and the conditions of sale."

He added that "virtually no liability may be assumed when the use of the chemical is not known to the supplier."

Because the chemical industry is characterized by variability with respect to products and their uses, customers, marketing procedures, and conditions of sale, the supplier must evaluate these factors for each product before meeting his responsibility for safe use, Dr. Adams said. Economically, it is not always feasible or effective to treat all chemicals alike. The producer of new chemicals must first obtain information on their chemical, physical, and physiological properties. Dr. Adams described three classes of tests to determine these.

Classes of Tests

Class 1 tests measure acute toxicity primarily, require but a small sample, cost but a few hundred dollars, and can be completed within 4 weeks. Their results form a basis for so-called handling precautions.

Class 2 tests are more extensive, yielding relatively precise measurements of acute toxicity and estimates of chronic toxicity, requiring about 6 months, and costing as much as 3 to 4 thousand dollars. They are conducted when the appropriateness of specific uses must be determined, or simply because of the wide distribution of an industrial chemical.

Class 3 tests are the most comprehensive and require hundreds of animals, or at times human subjects, 2 to 3 years for completion, and 30 to 40 thousand dollars. They are conducted when the use of a chemical requires a high assurance of safety and when a thorough understanding of toxicity is desirable because of widespread and diverse use.

The Manufacturing Chemists' Association has developed a system of labeling and promoting uniformity, the speaker stated. "The individual company has the task of designing proper labels and setting up procedures which assure the labeling of each container."

"The procedure of marketing may be utilized to assure the safe use of products which present hazards of exceptional seriousness and which require extensive precautions or pre-

cautions which are outside past experience of the customer," he said.

Occupational Diseases From Raw Materials

Surprisingly, occupational diseases associated with importation of raw materials into the United States have received comparatively little attention, commented Daniel C. Braun, M.D., medical director of the Industrial Hygiene Foundation, Mellon Institute, Pittsburgh, and John F. Osteritter, M.D., M.P.H., Graduate School of Public Health, University of Pittsburgh.

Limiting their discussion to a review of disease hazards from raw materials prior to processing, Drs. Braun and Osteritter said that handlers of raw materials are subject to many infections and infestations, numerous dermatoses, and certain pulmonary diseases such as asthma and pneumoconiosis. In addition, raw materials have been suspected of being involved in the causation of systemic diseases—notably cancer, and metal poisoning.

Human Anthrax

They named as one of the most common infectious diseases human anthrax, which occurs in all stages of the handling, transportation, unloading, processing, and weaving operations of wool and hair, and in the tanning of hides and skins. The incidence of industrial anthrax in the United States has shown a significant increase since 1939, attributable to increased importation of wool and hair for carpet manufacture, Drs. Braun and Osteritter indicated.

The reviewers listed other disease hazards in the infectious group: glanders and hoof-and-mouth disease related to the importation of livestock and derivative products; Q fever from handling goat hair, raw wool, dairy products, meat and stock; psittacosis from contact with birds of the parakeet family and their plumage; actinomycosis from contact with straw and certain an-

imals; "sealfinger," the colloquial name for a disease found among men who gather and handle seal pelts; and tetanus encountered in the handling of jute. Well's disease, pemphigus, tularemia, tuberculosis cutis, schistosomiasis, malaria, yellow fever, and filariasis are contracted from rodents and insects infesting ships and coming in contact with earwigs.

Dermatitis Sources

Insect infestation is a major source of dermatitis. The parasite *Pediculoides ventricosus* and related organisms are thought to be etiological agents for a variety of itches, they said. Grain itch appears in epidemic proportions among workers handling rice, barley, and wheat. The lesion is frequently seen on the faces and necks of workers who carry sacks of contaminated material on their shoulders. Water itch is found among coolies working on tea plantations and others who handle tea. Cottonseed itch occurs among workers handling contaminated seed in bulk quantities.

Hookworm is another pest, Drs. Braun and Osteritter indicated. Its larvae are often contained in bits of mud, causing contamination in the bags, barrels, or boxes of rice, cocoa, and similar materials from Japan, South America, Puerto Rico, and the East Indies.

Dermatoses also result from contact with vegetable fibers, plants, and woods, the reviewers continued. Among causative agents are the Japanese lacquer tree, the Indian marking nut, the cashew tree, and the Singapore mahogany, all members of the notorious poison-ivy botanical family. Lemon grass oil used in perfume and as an adulterant for lemon oil is a potent producer of dermatitis. Figs and bananas have also produced skin irritations. Other malefactors include lance wood, imported from Cuba, Brazil, and Guiana and used for wagon shafts and handles; boxwood, walnut, rosewood, and cocobolo wood from the West Indies; and ebony from Brazil.

Philosophies and Practices In School Health

Sessions of the American School Health Association's meeting in Cleveland dealt with a wide range of topics, including an analysis of the philosophy and principles of the school health program and a review of trends in mental and dental health and in school nursing. In an examination of school education, the scope and scheduling of instruction for grades 1 through 12 were considered, together with a consideration of the preparation and placement of health teachers.

Basic Principles Underlie School Health Programs

Man is an indivisible entity; a co-operative group effort is a necessity; and any phase of education must reflect and demonstrate the democratic way. These are the three basic considerations which "must underlie our thinking and planning in school health education," declared Delbert Oberteuffer, Ph.D., professor and chairman, department of physical education, Ohio State University.

Discussing these considerations, Dr. Oberteuffer pointed out that although the concept that man—the child or student—is a unified whole, "not a segmented animal," is not new, "only recently have we begun to understand this unity and to act in accordance with its meaning."

"Whatever is done in health education," he said, "whether it is the teaching of an activity for endurance, examining the mouth for dental decay, or requiring knowledge of immune processes, must be done in relation to the problem presented

by that whole and individual organism . . . The full measurement of value in health education is its production of good for 'me,' not for 'my eyes' or 'my weight' or 'my body.' In modern health education the concept of 'body' disappears. So does the concept of health education as good for any fragmented part. In its place is the evaluation of the effect of health education upon the individual as a person."

Responsibilities

The second principle Dr. Oberteuffer discussed concerned administrative jurisdiction, overlapping responsibilities, and uncertain boundaries. "There are so many of us involved [in school health programs]," he said, "that for years we have struggled with the curious element of protocol that seems to surround us when educators, physicians, nurses, dentists, and others try to work cooperatively in a cooperative program."

He urged that all concerned carefully examine the situation. "The school health program requires many people to make it operate suc-

cessfully," he said. "Responsibility for the health of youngsters belongs to all who deal with them. Many talents are needed—medical, educational, nursing, administrative, psychiatric, and more. Why argue about which talent is the most important? What we have to realize is that we are all important to the welfare of the child . . ."

Moral Values

The third consideration involves the moral values within the school health education program. "We must examine the relationship between school health education and the social and political philosophy of our people," he said. "Whatever we do in the name of school health education must meet the needs of the people. But in meeting those needs for medical care or for health advice . . . we must not destroy the capacity for self-direction and the will of the individual to look after himself and his family."

"But, withal," he concluded, "let none of us forget that school health programs exist because American school children have the right to the best that science can offer to aid in their development. The Nation has the right to expect that we who are strategically placed to aid them in this development 'will bring' every advantage to them."

Teachers Need Training In Mental Health Concepts

It is generally estimated that 1 school child in 10 is emotionally disturbed and would profit from clinical services, Louis Jacobs, M.D., M.P.H., a regional mental health consultant of the Public Health Service, stated in a discussion of remedial and preventive services in mental health in the school program.

Dr. Jacobs quoted from a study made by the Committee on Mental Health of the College Health Conference which found that "about 15 percent of all college students could be expected to benefit from mental health services. Of these, 5 percent would be considered urgent cases.

In some colleges and universities psychiatric and student counseling services are available as part of the educational system, Dr. Jacobs reported. Teacher training institutions in general, he believes, could make good use of remedial services for the persons who will become classroom influences on the emotional health of their charges.

Clinical services should also be available to the 10 percent in the elementary and high schools who need professional help, Dr. Jacobs said. Community-wide use of these services is indicated, he said, whether the clinic is part of the school system, the local health department, or another community agency.

Stresses Teacher Training

In speaking of preventive services, Dr. Jacobs stressed the importance of the teacher in the training of emotionally sound individuals. It is her understanding of children and her own maturity that determines the kind of job she will do in bringing out the best in her pupils, he said.

Much is now being done to give the teacher the information and practice she needs in understanding mental health concepts in the classroom, he said. For graduate teachers, a number of schools have in-service

training programs, institutes, and workshops where thousands of teachers have received instruction from psychiatrists, psychologists, and social workers. In teacher training colleges, the student health and counseling services are a valuable source of health education, he stated.

Dr. Jacobs recommended that physicians and nurses in the school health program receive similar indoctrination in the mental health field.

In addition to trained teachers and personnel, a school health program needs material with which to work, Dr. Jacobs stated. The workers need the preschool history of the child as well as cumulative records during his school years. They need complete examinations of the children, including an expert appraisal of their personalities.

By working for good facilities and services in every phase of health, by taking advantage of every educational opportunity, and by allaying fears and anxieties in their charges, health workers could make the schools a worthy second to the home in helping develop mature personalities, Dr. Jacobs concluded.

School Dental Programs Influenced by Research

Research in the field of dental caries prevention has been one of the factors significantly affecting school dental health programs, according to a survey of trends presented by Lester A. Gerlach, D.D.S., dental director, Milwaukee Health Department.

Dr. Gerlach noted that research in caries prevention has proceeded along two avenues of approach: the use of fluorides on the surface of the tooth, and the use of agents, such as ammonia, vitamin K, and others, to control the tooth's environment.

School dental health programs, he indicated, are aimed primarily at the prevention of dental caries through

the use of these newer techniques supplemented by a good educational program. "Both the fluoride water therapy and the topical application of sodium fluoride are becoming more of a reality all the time," he stated. "Although good, the fluoridation method of preventing dental caries is not a cure-all and must be augmented with a good dental health educational program."

The trend is toward streamlining the program and limiting the use of trained personnel as much as possible, he declared. The shortage of dentists and dental hygienists has made mandatory the use of aided workers and auxiliary personnel whenever feasible. He suggested that health educators, the school medical and nursing staff, and teachers can disseminate dental information.

A paramount consideration in future school dental health programs, he stated, will probably be the education of parents regarding the known caries preventives—their benefits and their limitations—and the encouragement of better dental hygiene in the home. There also exists a great need for attention to phases of dental health other than caries—malocclusions, malformations, crooked teeth, periodontal disturbances, infections, and oral manifestations of general systemic conditions, he concluded.

Study of School "Programs" Indicates Needed Revision

Ten suggestions for improving school health instruction programs were offered by Dora A. Hicks, M.A., chairman of professional health education, University of Florida.

From a review of the literature on current theories of health education and from a study of present practices in city schools as determined from replies to questionnaires, Miss Hicks concluded that attention should be directed toward the following measures:

Inform teachers, health personnel, and the general public of newer concepts in health instruction; improve school environments; conduct and promote original, organized health research among students, teachers, and community groups; establish college graduation requirements in basic health and hygiene for all students; include instruction in health education in certification requirements for teachers.

Also, provide regular school time for health planning and instruction; establish functional health committees in every school; evaluate and revise the health curriculum regularly; develop comprehensive State health teaching guides with suggestions for local use; and develop local health teaching guides that provide for articulation and continuity of health instruction.

Present Practices

Current methods used in developing health programs for grades 1-12 were investigated by sending questionnaires to the directors of curriculum construction in 75 large city schools, Miss Hicks reported. Replies, received from 39 schools, indicated how health needs were determined and how problem areas were selected, and listed the most neglected areas of health instruction and topics which should be included in a modern health education curriculum.

Briefly, the study revealed that:

Twenty-eight percent of the cities consider the use of State guides the best procedure for selecting problem areas, but 38 percent use a State outline or course modified to fit local conditions. Sixty-two percent of the cities indicated that it is best to use State guides as a resource only.

Sixty-two percent reported that it is not practical for individual teachers to determine the scope of health instruction because they are not qualified and because continuity cannot be accomplished by this procedure. The 38 percent in which individual teachers determine the scope pointed out that they should

work on various committees, with guidance, and should select units only within a basic framework.

Ninety-three percent indicated that their health instruction programs provide for articulation and continuity of instruction from grade to grade without unnecessary duplications or undesirable gaps.

Forty-five percent of the cities indicated that mental and emotional health was the most neglected area in their programs, and 21 percent reported insufficient emphasis given to sex education and to personal health.

Twenty-five percent of the cities listed as necessary topics for instruction: personal hygiene, mental health, sex education, nutrition, infection and disease, and body structure and function.

Urges Flexible Planning In Health Teaching

The need in grades 1-12 for health instruction on an equal basis with other important instruction was emphasized by J. Keogh Rash, Ph.D., chairman of the department of health and safety in Indiana University's School of Health, Physical Education, and Recreation.

Discussing the scheduling and se-

quence of health education in the school system, Dr. Rash said that proponents of the "continuous emphasis" plan reason that since the establishing of desirable habits is one of the major objectives of health education and can only result from repeated exercise, it follows that continuous emphasis must be placed on those habits which are to be encouraged.

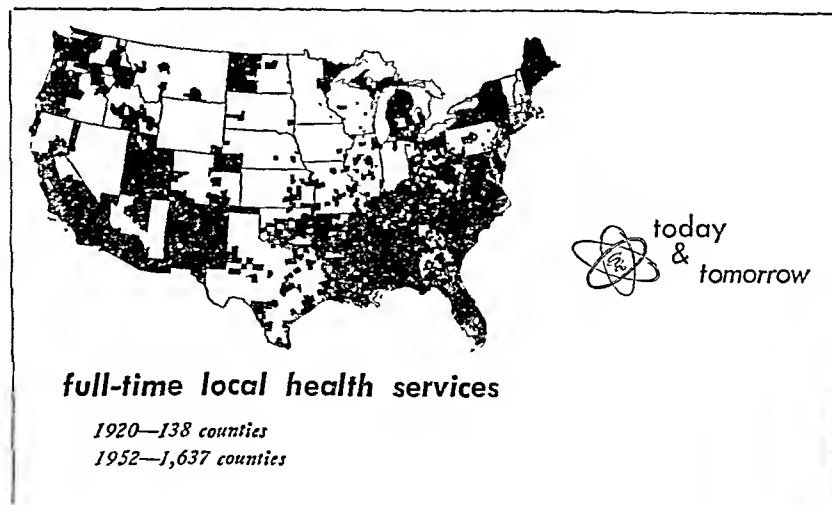

Supporters of the "opportunistic" plan propose using a psychological approach to health instruction, he said, explaining that a particular health problem is emphasized whenever the ideal opportunity for successful teaching offers itself.

Followers of the "cycle" plan seek to reinforce previous learning of special health problems by singling out a special health problem every few years for intensive study because of the growing child's changing needs, interests, and abilities.

In Practice

Each plan has its individual disadvantages, Dr. Rash said. The continuous emphasis plan is probably the oldest and most widely used; and the opportunistic plan has widest application in the kindergarten and first grade.

The cycle plan first appeared in the 1933 Indiana State course of study for elementary schools. Its first state-wide application was to all

grades in Oregon during 1945-46, he said. In 1948, Virginia adopted some of its principles. He continued:

"The new course of study in health education for Indiana, now in the try-out stage, suggests a combination of the cycle plan and the continuous emphasis plan. In certain problem areas, notably personal hygiene, the cycle plan is suggested while in other areas, notably nutrition, the continuous emphasis plan is suggested. The State law in Indiana requires instruction concerning the effects of alcohol and tobacco in grades 4 to 8, inclusive, so that the continuous emphasis plan will, of necessity, operate in this area during those years."

"The particular plan is not important," he concluded. "What is important is that there be conscious planning at the local level on the basis of the criteria of need, interest, comprehension ability, and ability to do for one's self. There must be sufficient flexibility to allow for continuous emphasis when necessary, and for use of the psychological approach when it seems desirable. In reality, the solution to the problem of scheduling and sequence rests not so much in a particular plan as it does with the planners."

School Health Activities In Cleveland Reported

The program of school health services offered in the Cleveland public schools was reported to the American School Health Association by Charles F. Good, M.D., director of school health services of Cleveland's board of education.

Emphasis is placed on prevention and early detection of deviations from good health, said Dr. Good. He felt that the primary responsibility for children's health is with the parents and that the basic role of school health programs is to assist medical and dental services already existing in the community.

Cleveland's school health budget has varied according to school enrollment, he continued, but it has gradually grown during the years.

In 1952 the over-all costs of school health services in Cleveland were \$3.80 per pupil, and costs of supplies averaged 4½ cents per pupil. However, these figures do not include special items of equipment which are acquired or replaced at times, even though the health service budget is part of the educational budget of the school system.

Health examinations of pupils—especially preschool examinations—have been stressed in Cleveland, said Dr. Good. He felt that such examinations are educational experiences, for parents may get advice on their children's needs from the school physician and nurse and then seek help from the family physician, dentist, or other community medical resources.

Follow-Up Stressed

But physical examination without adequate follow-up in each case of discovered disorder is fruitless, he continued, and in the Cleveland program the school nurse has the primary follow-up responsibility. She maintains a "work book" in addition to a permanent, accumulative pupil's health record card, and stresses the desirability of parental consultation with herself, a family physician, a teacher or principal, or appropriate clinics or specialists.

Besides general and special health examinations and the follow-up system, the Cleveland program provides also: eye and ear clinics for selected pupils; tuberculosis prevention and detection activities; dental examinations and mouth hygiene instruction; and psychiatric consultation for referred pupils.

The 24 part-time school physicians in Cleveland are assigned to one or more schools each morning during a week. When smaller schools are assigned to a physician he may divide his time among them or visit them on alternate weeks. Each physician has about 5,500 pupils in his weekly school assignment.

Nurses' assignments include a number of schools in adjoining neighborhoods with enrollments of about 2,200 children. Schedules are ar-

ranged to coincide with physicians' schedules. Time is allotted to each school so that schools of 500-600 enrollment have about 3 half-days of nurses' time each week and larger schools have more time proportionally.

At the present time, continued Dr. Good, the Cleveland school health program has no orthopedic diagnostic service. Most orthopedically handicapped children are now referred to and accepted at the Supbeam School for Crippled Children when unable to attend regular school. This school, he added, has an enrollment of about 140 children and serves the entire county. Besides the school nurse and physician, the school has four physiotherapists, a speech teacher, and numerous attendants, thereby stressing not only educational progress but also the adjustment of the handicapped child to adult responsibilities.

Field of School Nursing Is Reported Growing

The steady increase in the number of school nurses employed by boards of education—from 3,477 in 1937 to 6,088 in 1951—indicates that school nursing is becoming a specialized field of public health, averred Emily S. Brown, R.N., head nurse of the Elizabeth, N. J., board of education.

Other trends noted by Miss Brown were better preparation of school nurses, a closer alliance of the nurses with educational and school organizations, and an increasing drive toward organization themselves.

She felt that administration of school health services by boards of education is particularly desirable in large or moderate-size city schools. "School nursing cannot be conducted adequately unless the nurse's time is devoted entirely to the school," she declared.

In progressive school systems the school nurse is a health counselor, educator, and consultant—an important contributor to the child's educational experience, she continued. This, in turn, has drawn the

nurse into educational organizations to share in the over-all plans and objectives of the teaching profession.

Deploing the disparagement of specialized school nursing, Miss Brown declared that school nurses are not responsible for the alleged overlapping of public health nursing activities. They do not live in an "ivory tower," unaware of the needs and lives of the families of the children they care for, she said.

School nurses are not always able to satisfy their needs in regular public health nursing programs, she said. Many have to meet health teaching requirements and prefer to take work in health education, thereby having to sacrifice some areas of recognized public health nursing curriculums. She felt that school nurses should be accredited for study programs in health education as well as in public health nursing.

Miss Brown concluded that strong organization is needed among school nurses to better interpret their work to other public health groups and thus achieve greater recognized status.

School Health Education Viewed as Specialty

Teachers of English, history, music, or any other specialty are pinch-hitting as health instructors in our schools, according to Jennelle V. Moorhead, M.S., associate professor of health education, University of Oregon.

Lack of certification requirements for school health teachers allows school administrators to assign health courses to any teacher with a free period, she asserted.

In a study of the transcripts of 307 health teachers from 83 percent of the Oregon high schools, Miss Moorhead found majors in 31 different fields. Only 37 percent had majors in physical education, home economics, or biology, three of the fields recommended by national committees as suitable background for health teaching.

The newness of school health edu-

cation as a specialty has contributed to the lack of properly prepared health teachers, Miss Moorhead indicated. It has developed as a field separate from physical education since the late 1930's. Young people, who seldom see a health specialist at work, do not think of health education as a career, she said. Even vocational counselors in high schools and colleges may not regard it as a field of specialization.

Few institutions of higher education offer a bachelor's degree with a major in health education—only 41 of the 1,688 institutions surveyed by the Office of Education in 1949, Miss Moorhead continued.

Although schools generally agree on the basic subject matter of the courses offered, they differ on course scope and content and on the number of credits needed to insure competence as a specialist, she said.

534 Health Topics

As an indication of what the health teacher should know, Miss Moorhead cited an analysis of the Oregon course of study for health. This showed that the Oregon high school health teacher is expected to teach 534 separate health topics in the nine major health units—personal hygiene, community health and sanitation, communicable disease, nutrition, mental health, first aid and safety education, choice and use of health services and health products,

physiology of exercise, and structure and functions of the human body.

Sixteen training courses, Miss Moorhead found, were important in determining how well prepared the teachers were for health instruction. She recommended that other States make a similar job analysis for their health teachers.

After training the health education major, we must also place him, Miss Moorhead stated. School administrators have stressed the importance of health subjects, but in actual practice they do not designate a place on their staffs for a health specialist, she declared, explaining that the situation is further complicated when people in the field of health education recommend the integration of health education into other areas in the high school curriculum.

To obtain for health education its proper status in the schools, health educators must first agree on a course of study for training health teachers, Miss Moorhead concluded. They must offer concrete suggestions on what is to be taught in various grades and how it is to be taught. They must sell school administrators on the importance of health education. And they must get young people interested in school health education as a profession through work with parent groups and with high school and college guidance personnel.

the health of
mother and child

Maternal and Infant Mortality Surveys and Evaluations

As a factor influencing maternal and infant mortality, anesthesia was mentioned frequently in the sessions of the maternal and child health section. This factor appeared of significance in a study of the premature born in a Kansas hospital and in one reporting the results of a Minnesota survey. In another presentation before the section, a report was made on the quantitative adequacy of prenatal care in a middle-sized community.

Probe of Specific Factors In Infant Death Advised

Research on the causes of infant mortality should henceforth be concentrated on hygienic practices, "mothercraft," and similar factors within given income and occupational groups, Odin W. Anderson, Ph.D., associate professor in charge of the social aspects of medicine, University of Western Ontario, Canada, believes.

Dr. Anderson indicated that further research on the general relationships between infant mortality and income level, class, and occupation would be a waste of time, money, and effort. The general social factors affecting infant mortality have been conclusively established, he said. A synthesis of the profuse data on infant mortality during the past 100 years, and in more detail the past 50 years, shows clearly that a high infant mortality rate is associated with poverty.

Enlarging on known facts, Dr. Anderson stated that mortality rates began to drop perceptibly in many

countries at a certain stage of their technical development. In fact, it would seem reasonable to assume that when the infant mortality rate in any area falls below 30 per 1,000 live births, he said, the economic factor becomes less and less operative as a general cause of mortality, and other factors, such as mothercraft, intelligence, personality, and specific hygienic practices, become more operative.

Dr. Anderson suggested that any further search efforts be directed at this complex of factors within specific groups.

Feeling of Personal Worth Basic in Prenatal Care

A sense of personal dignity and worth that prompts women to seek care early in pregnancy is a prerequisite to an effective prenatal care program, a study sponsored by the Rochester Health Bureau and the University of Rochester School of Medicine and Dentistry, New York, found.

Making the study of the quantitative adequacy of prenatal care in the medium-sized urban community of Rochester were Alfred Yankauer, M.D., M.P.H., director of maternal and child health services, New York State Department of Health, and Kenneth G. Goss, M.D., and Salvatore M. Romeo, A.B., public health interns of the department.

Most of the women, regardless of economic status, sought early aid, but a small number of women of low socioeconomic status neglected to seek care until late in pregnancy, the investigators reported.

Socially Disorganized

A study of a group of socially and economically underprivileged women

who failed to get early prenatal care revealed a greater degree of social disorganization in comparison to a group of similar status who sought care. In the study group there were more out-of-wedlock births, greater mobility and fertility, and a greater degree of welfare dependency. The incidence of birth weights of less than 2,500 grams and of neonatal deaths was significantly higher in this group.

The investigators concluded that the women with adequate care were able to translate their feelings of personal worth into sound health practices and bear healthy children. Failure to seek prenatal care, they termed an outward manifestation of the rejection of pregnancy and the loss of a sense of personal dignity. These attitudes affect the fetus adversely by way of maternal nutrition and pattern of living, they stated.

Helping these women attain a sense of dignity and worth is a task confronting the community as well as the public health and social worker before prenatal care techniques and knowledge can be effective, they said.

Minnesota Survey Reveals Lower Maternal Mortality

The reduction in the maternal mortality rate in Minnesota from 2 in 1941 to 0.3 per 1,000 live births in 1951, although a great improvement, is not the maximum possible, according to A. B. Rosenfield, M.D., M.P.H., director of the division of maternal and child health, Minnesota Department of Health.

In many States maternal mortality rates are now lower than was thought possible 10 years ago, but surveys show many maternal deaths could be prevented, he said.

The Minnesota survey of 1941-42 was resumed in 1950 and is now in its third year. Eight physicians selected by the maternal health committee of the State medical association

tion in addition to Dr. Rosenfield are on the committee conducting the survey.

The survey includes in its coverage all women who die during pregnancy or within 3 months postpartum, regardless of the actual cause of death. A State health department regulation helps the committee get prompt notification of maternal deaths. An obstetrician investigator visits the hospitals and reviews charts, nurses' notes, anesthesia records, and pathologists' reports. The investigator also interviews hospital personnel, visits the attending physician and obtains the history, including prenatal care. He interviews the consultant, if there was one, and relates if data is needed from them.

The committee reviews the investigator's report, and its determination of cause of death is mailed to the attending physician and to the consultant.

The 1950 survey showed (in comparison with the 1941 survey) a 40-percent increase in the number of live births, a 35-percent increase in the number of hospital births, and an accompanying decrease of 70 percent in maternal mortality. Marked improvement was noted in prenatal, delivery, and postpartum care although some deaths were still attributable to faulty care.

Dr. Rosenfield asserted that anesthesia is becoming a more important factor in maternal mortality. In 1941, he said, anesthesia was responsible for three deaths (3.2 percent) but accounted for four deaths (8.7 percent) in 1950. However, anesthesia contributed to 12 additional deaths.

Other significant survey facts were: Consultations increased from 44 percent in 1941, with 9 percent considered adequate, to 57 percent in 1950, with 32 percent considered adequate. Over half the deaths in both years occurred in women who had operative deliveries. In 1941 three-fourths of the maternal deaths were considered preventable; in 1950 only one-third were considered so, he said.

Use of Analgesia Opposed In Premature Labor

"The use of analgesia in known premature labor deserves nothing but condemnation," declared Russell A. Nelson, M.D., of the Wichita Foundation of Medical Research, and Francis E. Barry, M.D., Maj., U. S. Air Force, Lackland Air Force Base, San Antonio.

They stressed that drug depression by any analgesics, hypnotics, sedatives, or anesthetics may cause anoxia of the premature and that medication effects are more profound in the fetus than in the mother. If general anesthetics must be used, they recommended nitrous oxide and oxygen, no stronger than 80 percent nitrous oxide.

The physicians felt that painless labor produces threats to the infant and should not be offered. Short labors with some relief will give infants in better condition, they said.

Their conclusions were based on a study of all liveborn infants from 500 to 2,500 gm. born in 1949 and 1950 at St. Francis Hospital, Wichita, Kans. The hospital's incidence of premature births is about 7 percent, with a death rate for this group of 21.8 percent.

Regarding the use of analgesia and its effect on 246 perineally delivered prematures studied, they reported

that no infant under 1,000 gm. receiving analgesia survived while 50 percent of those receiving no analgesia did survive. From 1,000 to 1,500 gm., 75 percent of the infants without analgesia survived, compared with 56.3 percent of those having it. All in the 1,500 to 2,500 gm. group receiving no analgesia survived. Of those having analgesia, the death rate was 20.9 percent for the 1,500-2,000 group and 9.5 percent for the 2,000-2,500 group.

Warn Public

Public health programs should warn the public of the danger of heavy sedation and general anesthetic for delivery of the average baby, they said. They advocated more attention in medical schools to premature labor and immediate care of premature infants.

Most anoxic and atelectatic infants die in 24 hours, they continued. They felt that both the general practitioner and the specialist should be adept at resuscitation, including tracheal intubation and aspiration. When infants are delivered in poor condition, oxygen and an airway are of primary importance, they emphasized.

The doctors felt that death conferences should be held in all hospital obstetrical departments, just as surgical material is examined for pathology.

Water Fluoridation Programs And Community Health

The water fluoridation program and community health were discussed at a joint session of the APHA sections on dental health, public health education, and public health nursing with the American School Health Association and the Conference for Health Council Work. Topics included an appraisal of the water-borne fluoride-to-dental caries relationship, toxicological evidence of safety in the use of fluorine techniques and a statement on the public health nurse's role.

In another session, the engineers looked at fluoridation in terms of benefits, safety, and current practices. In still another session public health dentists discussed the prefluoridation base-line survey and also considered the effect of topically applied stannous fluoride on caries experience.

Research on Fluorides A Continuing Project

Continued and even expanded research on the relation of fluorides to dental health was recommended by H. Trendley Dean, D.D.S., director of the National Institute of Dental Research, Public Health Service.

Although fluoridation of public water supplies for the partial control of dental caries is an accepted public health procedure, a public health problem can never be considered closed, Dr. Dean asserted.

In presenting the current status of fluoridation, Dr. Dean said that nearly 8½ million residents of 427

communities, distributed among 42 States and the District of Columbia, were using fluoridated water supplies by September 15, 1952. This preventive measure had been approved and plans were under way to start the program in an additional 299 communities with more than 15 million residents, he said.

Dr. Dean noted that extensive research has accompanied the program. The inquiry into the effect of fluorides on dental caries expanded into many areas heretofore thought far removed from dental hygiene, he said. He named as among the specialized fields profitably used in the systematic development of the study: basic research in analytical water chemistry, physiology and biochemistry, biometry, pharmacology, histology and pathology, microbiology, dentistry, medicine, public health, sanitary engineering, and water works operation. Explored to a lesser extent but nonetheless important, he said, were geology, hydrology, climatology, veterinary medicine, physical chemistry, and biophysics (radioactive isotopes, electron microscopy, and electron diffraction).

Further research can perhaps improve the effectiveness of fluorides, Dr. Dean concluded, and there remains further exploration of the response of a mass population to a changed physiological environment.

Nurses Have Teaching Role In Community Fluoridation

The public health nurse has a major educational role in a community water fluoridation program because of her direct relationship with the individual, the family, and the community as a whole, said Esther A. Sehisa, R.N., B.S., public health

nursing director of the Ulster County Health Department, Kingston, N. Y.

The addition of the water fluoridation program to public health dentistry merely necessitates equipping each nurse with knowledge of the relationship of fluorides to dental caries, she continued. The nurse, who more than most directly interprets a health department program, must then not only emphasize the importance of good nutrition, cleanliness, supervision by a dentist, and other aspects of dental health, but also must understand the techniques of water fluoridation, the community need for the program, its costs, practical aspects and effectiveness, and methods of control.

Miss Schisa emphasized that the public health nurse should maintain an objective viewpoint toward water fluoridation regardless of her personal sentiments and beliefs.

Toxicology Tests Show Fluorides to Be Safe

Replying to critics of fluoridation, Francis F. Heyroth, M.D., assistant director of the Kettering Laboratory, University of Cincinnati College of Medicine, said that toxicological evidence assures the public that it can safely drink from communal water supplies containing optimal fluoride concentrations.

Unless public health authorities inform the public of the evidence upon which they base their beliefs in the safety of fluoridation, many will accept statements that little is known of the toxicity of fluorides or that the epidemiological evidence relied upon by fluoridation advocates fails to reveal adequately any adverse effects that may be associated with individual variations in susceptibility, Dr. Heyroth stated.

He outlined in some detail the extensive toxicological evidence now available and paid particular attention to acute and chronic toxicity, histological and histopathological changes in animal experimentation.

industrial human fluorosis as well as the experiments with human cases.

He pointed out that animal experimentation shows that the prolonged intake of quantities of fluoride too small to induce dental fluorosis does not give rise to any of the nondental manifestations of chronic intoxication by fluorides. Epidemiological data and clinical and radiographic examinations of exposed industrial workers indicate that only when the fluoride content of a water supply exceeds 5 or 6 ppm will its prolonged usage give rise to detectable osseous changes, and then only in the most susceptible persons, the laboratory director reported.

Toxicological Experiments

There need be no fear of acute poisoning as a result of the accidental or deliberate overfluoridation of a water supply, Dr. Heyroth emphasized. The only toxic hazard to be associated with fluoridation would be that of the cumulative action of small amounts taken daily over a long period, he asserted. The lethal dose in rabbits is 50 to 200 mg. of fluoride ion per kilogram of body weight. In human self-experimentation, as much as 250 mg. of sodium fluoride has been taken at one time without harm, he stated.

"It may be concluded from the results of animal experimentation that interference with growth cannot be induced by a daily intake too small to give rise to dental abnormalities and that only after the bones have stored considerable quantities of fluoride does any impairment of skeletal function occur," he said.

For the past 12 years, the Kettering Laboratory has conducted painstaking investigations to learn the rates at which storage in human bones occurs when known amounts of fluorides are ingested daily. By analyzing duplicate amounts of all food and liquids ingested daily by selected subjects over prolonged periods, the average daily intake of fluoride of each subject was measured. Two were found to have in-

gested 0.49 and 0.72 mg. of fluoride per day, and appeared to be in metabolic balance with respect to fluoride. One of the two ingested 6 mg. of extradietary fluoride (sodium salt) per day over a period, and retained the equivalent to 0.095 mg. per kilogram of body weight. Over a long period, two others took daily doses of sodium salt, equivalent to 0.05 and 0.14 mg. per kilogram respectively. In neither subject have radiographic changes occurred in the density of the bones, although one took more than 20 gm. of sodium fluoride during a period of 120 weeks.

Dr. Heyroth referred to the brief balance experiments, in which an attempt was made to measure elimination through the skin, and the conclusion that when daily intake did not exceed 4 or 5 mg. the major portion was eliminated from the body.

Panel Summarizes Data On Water Fluoridation

Introducing a panel discussion on fluoridation, Charles R. Cox noted that its purpose was the summarization of accumulated data on the subject. Mr. Cox is chief of the water supply section, bureau of environmental sanitation, New York State Department of Health.

The public health administrator is confronted with the need for answering the medical, dental, and toxicological arguments against fluoridation which have been brought forth by some groups and individuals, and the public health engineer and the water works official have the problem of establishing satisfactory procedures and controls for the fluoridation of potable water supplies, Mr. Cox pointed out.

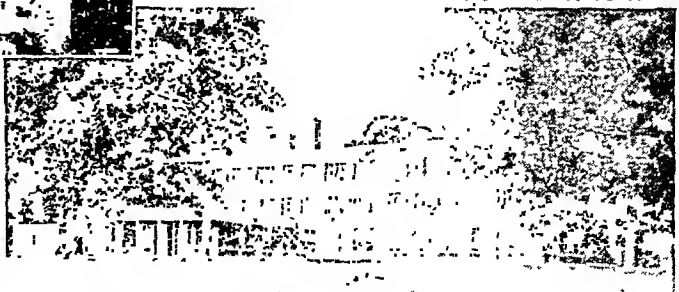

He assigned the problem of appraising the medical, dental, and toxicological data to the specialists in these fields. A recent statement by the board of directors of the American Water Works Association, reaffirming and augmenting their policy announced in 1949, clearly supports the attitude that the fluoridation of public water supplies represents a dental health program, the basic policy for which rests with medical and dental health directors, he said. It is significant, he observed, that the fluoridation of public water supplies is supported by the following associations of responsible public health administrators: State and Territorial Health Officers Association, State and Territorial Dental Directors Association, American Association of Public Health Dentists, and the Conference of State Sanitary Engineers.

Mr. Cox also pointed out that the technical data resulting from re-

today
&
tomorrow

**tuberculosis case finding
and treatment**

search and experience have led the following national technical associations to support the fluoridation of public water supplies: American Public Health Association, American Medical Association, American Dental Association, and National Research Council. Clearly, he said, these organizations did not give their support lightly but only after careful study.

Taking part in the panel were David B. Ast, D.D.S., director of the bureau of dental health, New York State Department of Health; Julius S. Cass, D.V.M., Kettering Laboratory, University of Cincinnati College of Medicine; John M. Hepler, C.E., director of the division of engineering, Michigan State Department of Health; and Norman E. Jackson, whose presentation is reported below.

Nation's Capital Begins Fluoridation of Water

Fluoridation of the Washington, D. C., water supply in the amount of 1 ppm began in June 1952 with the opening of the Dalecarlia filter plant, reported Norman E. Jackson, M.S., chief of the Washington Aqueduct's Dalecarlia section in the Washington district of the U. S. Army Corps of Engineers.

Mr. Jackson traced the development of the fluoridation program from its origin in the District Department of Health's bureau of dental services through its consideration by District departmental, public and governing authorities to its review by Congress and final enactment into law. He then made the following observations from experience at the Dalecarlia plant:

Large installations should order sodium silicofluoride (the fluoride agent used in Washington) in carload shipments of large drums rather than paper bags, because of the quantity necessary and the toxic dust hazard in bag breakage. Vacuum pneumatic handling of the agent with properly designed, in-

stalled, and maintained equipment practically eliminates the dust hazard, but protective personnel equipment and clothing also should be used as a safety precaution.

The tendency of sodium silicofluoride to conglomerate into lumps during storage can be partially reduced by filling the storage bins to only 10 percent of capacity, thus reducing weight and detention period. This procedure, however, does not solve the problem of large tonnage storage. Should bins or hoppers with sloping bottoms be used, the minimum angle should be 60 degrees with the horizontal. A more desirable installation and a better gravity flow will be achieved if bins and hoppers have one vertical side.

Screening Urged

Before being introduced to filtered water, the fluoride solution should be adequately screened for foreign matter. In the installation of piping, hard rubber pipe is recommended for rigidity needs and polythene-base plastic pipe for flexibility and non-corrosive qualities.

Although not proved conclusively, alum flocculation seems to adsorb the fluoride. With medium dosage of 1.1 gr./gal. the adsorption loss is only 5 percent, but with high alum dosage of 2.5 gr./gal. the loss may reach 30 percent. Adsorption loss in reservoirs and distribution is inconsequential.

The chance of overdosage of fluorides is negligible, provided there is proper equipment and alert and competent supervision.

Conduct Base-Line Survey Before Planning Program

"The promotion, institution, and evaluation of fluoridation are presenting unique opportunities for a fresh approach to the establishment of community dental programs and enhancing their likelihood of success," said Norman F. Gerrie, D.D.S., M.P.H., Public Health Service, Denver, Colo.

In discussing the planning of community dental programs, Dr. Gerrie emphasized that the prefluoridation base-line survey gives the community its best means of obtaining authoritative information on its current dental health status. No dependable plan for a dental health program can be constructed without such facts, he said.

He pointed out that the inclusion of the local dentist in the base-line survey will help the dentist to see first-hand the status of his community's dental health and to understand better the statistical and public health significance of the data. It will also enable him to participate more actively and authoritatively in the planning of a program to fit the needs of the community and to recommend program content consistent with his inclinations and abilities and the community resources. The public health dentist should act as consultant and catalyst in such surveys, Dr. Gerrie added.

Outlines Steps to Program

In forming a community dental program with both short- and long-range objectives, the following steps were recommended:

1. Securing base-line dental caries data by a community survey. If there are no local practicing dentists to make the survey examinations, the services of a public health dentist or private dentists from nearby communities should be used.
2. The data should be processed, analyzed, and interpreted by the public health dentist in detailed reports to the local dentists and to a local committee of responsible citizens. The data should be easily comprehensible and accompanied by charts, graphs, and recommendations.
3. At subsequent meetings of the committee, which should include dental representation, a program should be formulated with objectives and methods chosen according to the extent of the problem, the desires of the groups and individuals involved, and the resources of the community.

4. A critical, periodic evaluation of the program to measure progress toward objectives.

Stannous Fluoride Reduces Tooth Decay in Children

A 56-percent reduction in the number of newly decayed teeth was noted in children whose teeth had been treated topically with stannous fluoride, compared to a control group of children who had received a dental examination only, reported Charles L. Howell, D.D.S., M.P.H., Charles W. Gish, D.D.S., and Roy D. Smiley, D.D.S., assistant director, dental consultant, and director, respectively, of the division of dental health, Indiana State Board of Health.

Four groups of children in Bloomington, Ind., were studied in 1951 to determine the effectiveness of stannous fluoride in preventing tooth decay in the permanent teeth of young children, the dentists said. The first group of 210 was treated with sodium fluoride; the second group (382) was treated by use of the same technique with stannous fluoride; the third group (409) was treated with stannous fluoride using a different method mainly keeping the tooth surfaces moist during treatment; and a fourth served as a control group. Both stannous fluoride groups had a higher ratio of teeth recorded as carious in 1951 and noncarious in 1952 than either the sodium fluoride or the control group.

Compared to the control group, the reduction in number of newly decayed teeth after 1 year was 54.8 percent for the first group, 56.4 for the second, 53.6 for the third, according to the report.

Keeping the surfaces of the teeth moist throughout the treatment period did not increase the caries-reducing potential of stannous fluoride under the conditions of this study, they stated.

Dr. Howell and his colleagues

recommended assignment of children to treatment groups by age and previous dental caries experience rather than by random distribution of numbers, which they said resulted in groups unequal in age and in numbers of decayed, missing, and filled teeth.

No Evidence of Pathoses From Fluoride Ingestion

"Objections to fluoride ingestion from water supplies as productive of various pathoses have had no support beyond vague 'might be' or 'could be' or 'we don't know' expressions," declared Frederick S. McKay, D.D.S., Sc.D., of Colorado Springs, who first traced "mottled enamel" to heavily fluoridated natural water supplies.

"The best informed scientific opinion available is emphatic in declaring that there is no submitted evidence of any pathoses associated with such fluoride ingestion," he continued in his discussion of the relationship of water-borne fluorides to dental caries.

Fluoridation is a natural phenomenon and not an experiment, he asserted, and recalled that its discovery came in a study to find the cause of "mottled enamel." The low amount of caries that went with

mottled enamel was not recognized for many years.

Dr. McKay pointed out that 23 States have naturally fluoridated water supplies, some with as much as 3 ppm and more as against the recommended 1 ppm, and no evidence of damage to the inhabitants has been uncovered. He noted that such places would be ideal for finding evidence of illness caused by fluoridated water.

Fluorosis, even to an extremely disfiguring degree, can be produced when the fluoride content is 2 ppm or more, but the caries experience rate may be and often is low. However, there are persons who use water with 2 ppm of fluoride and higher with no visible fluorosis and a low caries experience rate. Although there is no explanation for this, it is of extreme importance, he stated, that this "not visible" fluorosis has a caries resistance equal to that of visible fluorosis.

Dr. McKay credited the Public Health Service studies with establishing the relation between fluoridated water and the dental caries rate. When the fluoridation of our water supply becomes general throughout the country, he said, the dental profession will be within "striking distance toward control of the damage to and loss of the teeth by caries."

Field Research and Appraisal In Health Education

Planned, organized, objective investigations of the "why" of health education are becoming more frequent, reports to the APHA of going projects revealed. In a symposium on "current research affecting public health education" as well as in other sessions, some dozen presentations were made. Those for which texts were available are summarized here

Use of Behavior Knowledge Underlies Program Success

There is no better place than the field of public health to put to use available knowledge on why people behave as they do, in the opinion of Naney Starbuck, Ph.D., education psychologist in the Division of Dental Public Health, Public Health Service.

Three principles of human behavior which seemed applicable to the problem of community organization were tested in six communities previously visited by a topical fluoride demonstration team. Dr. Starbuck stated that three communities had established continuing programs after the teams had left; three had not. The research problem was to find out why some community leaders set up continuing programs and others do not, she reported.

To reach a decision to initiate and carry out a program, Dr. Starbuck said, community leaders must regard it as a means of solving a problem and an aid to accomplishing their own objectives, as well as feeling that they have initiated the program and that others in the community want it. Community leaders and program administrators must agree

on its purpose, and objectives, and accept the methods employed, she stated.

How Principles Operate

In the communities which continued the programs, the leaders saw a direct relationship between their own objectives and those of the program, and reported that the demonstration team had been invited by the local people or through local and State officials, she said. Community groups had been solidly behind the leaders both in requesting the team to come in and in continuing the program after its departure. Most community leaders realized the long-range purpose of the program and had discussed continuing it after the team left. "Logical" groups—dentists and physicians, city and school officials—predominated in the planning.

In the three communities which did not continue the program, Dr. Starbuck said that local people had had no part in the decision to invite the demonstration team; they did not support the leaders; they had no appreciation of the long-range objectives of the program; the planning group was composed largely of civic groups, PTA's and fraternal organizations; and the leaders did not like the methods used.

Michigan Tests Response To Survey Publicity

Janitors and caretakers in semi-slum areas may play an important role in getting their tenants—especially the foreign-born tenants—to have their first chest X-rays.

This case-finding clue was reported by Norbert Reinstein, M.P.H., director of the Tuberculosis and Health

Society of Detroit during a study of factors which influence people to have X-rays. Using health department sanitarians as emissaries, an educational program was launched to enlist the support of janitors and caretakers in the next X-ray campaign. Result: In an area where only 110 foreign-born persons had been X-rayed in previous years, 553 turned out for X-rays after the new approach was tried.

The media for the X-ray educational programs in Wayne County are the local newspapers, leaflets, churches, schools, and home visits, Mr. Reinstein stated. The results of these phases of the program were studied when community attendance to the X-ray mobile truck decreased.

Former Campaigns Studied

Campaigns in 1949 and 1950 in Hamtramck, Highland Park, and Dearborn were evaluated. Graduate students of the University of Michigan Institute of Social Work volunteered to conduct the study. It was found that in all communities the newspapers were the most frequently mentioned source of information, Mr. Reinstein reported. The most effective personal sources of information were the churches in Hamtramck; the schools in Highland Park; and home visits in Dearborn. The only general conclusion was that the campaigns had influenced

Valuable clues in the quest for chest X-ray, Mr. Reinstein said.

Valuable clues in the quest for improving the X-ray publicity in Wayne County were shown to be:

1. A group of 110 foreign-born persons came for their first chest X-ray through direction of janitors of the rooming houses in which they lived. Health department sanitarians inspect the houses regularly and the janitors and caretakers seem to be influential with the foreign-born residents. At the same location during the next survey, 553 of these persons came for X-rays.

2. Persons had stayed away from being examined though they had

been reached. It was found that untrained volunteer workers failed to motivate them.

3. Distribution of leaflets by Boy Scouts was not as effective in one community as home calls by adults which in another locality brought twice as many persons to the trailer.

4. The site chosen for the X-ray trailer was very important.

5. Enlistment of the private medical practitioner and the community dentist is valuable and often the means of local success.

A Pre-evaluation of Pierre the Pelican

Accepting Knutson's principle that evaluation should precede wide distribution of any education material and that a field test constitutes a final criterion in the process of evaluation, Bernard G. Greenberg, M.D., and his associates attempted to find what impact a certain mental hygiene pamphlet would make upon parents of first-born children in North Carolina.

Pamphlets Distributed

The series of pamphlets "Pierre the Pelican" prepared by Loyd W. Rowland for the Louisiana Society for Mental Health was widely distributed throughout Louisiana in 1947. Designed to cover good principles of child rearing beyond the area of physical care, they are, according to the author's statement, characterized by simplicity, cast at the sixth-grade reading level, illustrated by sketches, and comprised of a series of 12 pamphlets, one to be sent out each month. The series attempts to cover topics of interest to young parents, is of optimal length, and makes use of questions for teaching purposes.

The North Carolina State Board of Health, before embarking upon a permanent program of distribution, asked Dr. Greenberg, C. Frances MacKinnon, M.S., and Sidney S. Chipman, M.D., all members of the

faculty of the University of North Carolina School of Public Health, and Mary Ellen Harris, M.S., of the Institute of Statistics at Raleigh, to make a study of the pamphlet's effectiveness.

The study group tried to find the answers to these questions:

In North Carolina, will the pamphlet fulfill the purpose for which it was intended? Will it be equally effective for all demographic groups in the State? Will its effectiveness, if any, justify the cost and effort involved in its distribution?

To answer these questions an experimental and a control group were set up in 17 counties in North Carolina, selected to give a cross section of the population. Pamphlets were sent to members of the former but not to those of the latter group. In a few instances control families obtained one or more issues of the pamphlet. Replies from these families were taken into consideration in analyzing the data, the report explained. A questionnaire schedule was formulated and interviews, arranged for at well-child conferences, were wire recorded.

Reception Favorable

Approximately 2,200 home interviews were conducted with mothers to ascertain through questioning their attitudes and practices regarding infant feeding. While the re-

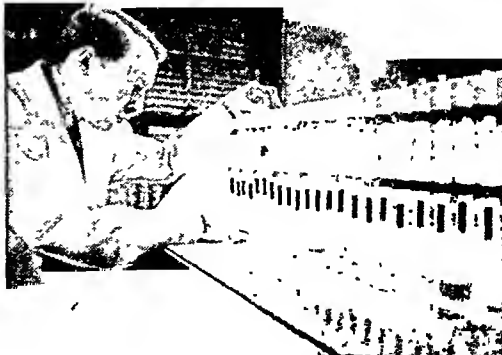

sults are not clear cut, the data suggest that "Pierre" had relatively little or no beneficial effect upon feeding practices.

"There is no question," the researchers said, "that 'Pierre' was favorably received." Replies to a questionnaire indicate that parents favor continuing the series. In fact, 90 percent of those who answered said they were saving the pamphlets. The preliminary evidence nevertheless raises a serious question about routine gratis distribution of "Pierre" or any similar material, the study group concluded. "An explanation for the apparent failure of 'Pierre' to modify behavior patterns is still not provided."

Pretesting of Materials Increases Usefulness

By pretesting our health education materials in rough form, "we can find out whether they make good sense to persons who have experiences different from our own," said Andie L. Knutson, Ph.D., chief of the experimental and evaluation services branch in the Division of Public Health Education, Public Health Service.

He defined pretesting as a means of obtaining the other man's perception or interpretation of a message

today
&
tomorrow

research

*laboratory
field
social
clinical
administrative*

so that changes can be made to take into account his pattern of understanding and his way of life.

Dr. Knutson cautioned that any pretest technique used should be focused on the reactions of individuals similar to those for whom educational materials are intended. Persons of different economic, social, and educational levels, he commented, vary so widely in experiences, wants, and values that they cannot view all social situations alike.

Tests Identify Barriers

"We have found it useful to plan pretests so that they yield information about potential barriers to effective communication," he said, adding that "pretests will help to identify these barriers," and steps can be taken toward a successful program.

Dr. Knutson pointed to the value of applying objective readability tests and word lists to materials in their developmental stage for determining whether words and concepts have a common meaning.

Members of the intended audience should review the material, he said. Their responses would be helpful in overcoming misunderstandings and obscure portions.

Exhibits and Posters

An exhibit or poster intended for wide distribution should be pretested in a situation similar to the one in which it will be used, Dr. Knutson continued. He suggested that an observer stand with a stop watch some distance away from an exhibit or poster to record how visitors behave during a given period of time: How long do they stop? How does this time compare with the time it takes to view the exhibit completely? What are their comments?

He further suggested a few simple questions to ask visitors as they leave an exhibit: Why did you stop to look at the exhibit? What did you expect to see? What did you find most interesting, least interesting? What would you like to know more about?

Also to be considered, the social psychologist added, is whether people find something in the information to satisfy their wants. But "it is not sufficient for health education to tie in with existing patterns of motivation," he commented. "What is presented must help individuals to achieve health goals with a minimum of disruption of their ways of life. It is unreasonable to expect new practices to be readily accepted if they conflict with deep-rooted habit patterns. At the same time, it is wasteful to re-educate more than is necessary to achieve adequate improvement in health behavior."

Pretests are most helpful when a program is being developed, but they cannot replace exploratory studies nor substitute for sound evaluation, he concluded.

Adult Education Group Defines Interests

The Adult Education Association, comprising specific interest groups and having geographically distributed administrative centers, offers a common meeting ground for those interested in any aspect of adult education, including public health education, declared Fern Long, Ph.D., adult education supervisor of the Cleveland Public Library.

Dr. Long felt there is complete agreement among interested organizations about the ultimate objective of adult education, which is "the development of a citizen body of free men and women, alert to the issues of this time in which we live, informed, thinking, questioning, relating thought to action and action to thought. Indeed, a democracy cannot be viable without that kind of citizenry," she said, but warned that "although the objective may be so simply stated, the achievement of the objective is far from simple."

Information Clearinghouse

This new (1951) organization wishes to be broadly representative

of educational groups, she continued, in explaining the structure of the Association's Council of National Organizations, a group of national organization representatives, including the APHA, which meets periodically for special objectives. The council can be a clearinghouse of information, she said, and, through a news letter to various organizations, a medium for exchange of ideas, materials, and methods.

Organization of adult education on State and regional levels has been made possible by a 3-year Ford Foundation grant, Dr. Long reported. Conferences will be held to discuss, and explore ways and means of developing adult education on those levels, she said.

"Machine Thinking" Hazard To Health Education

"Machine thinking" was termed by Mayhew Derryberry, Ph.D., as one of the pitfalls facing health educators in their task of persuading people to change their health behaviors.

Dr. Derryberry, president of the Society of Public Health Educators, and chief of the Division of Public Health Education of the Public Health Service, spoke at the second annual meeting of the society.

He cited the frequently encountered mechanical step-by-step directions for organizing community health education programs, which are distributed as a packaged program with accompanying news releases, radio scripts, and posters.

"The machine—the mass producer of progress," as one of our cultural symbols, has already conditioned some of the methods that have been tried, such as the wartime job instructor training, he said. Dr. Derryberry explained that he was not endorsing a haphazard solution of problems but was questioning blind application of rigid mechanical procedures to human beings, personalities, and communities, each

with unique experiences, goals, aspirations, and ways of working.

Administration vs. Performance

A second hazard, he said, is the tendency to be more concerned with administrative structure than with the work to be done.

Communities, he explained, are urged to organize councils of every description, using a specific structural pattern similar to that of some other organization. The structural pattern may include items about membership, representation, administration, committees, by-laws, and so on.

"Any administrative arrangement is acceptable," he said, "if it permits and encourages the health education staff to work jointly and effectively with all other agency personnel in the planning and execution of the program."

Dr. Derryberry named as other hazards, the development of a jargon which has meaning to the profession but not to the laymen outside, use of a familiar technique for widely varying situations, and the tendency among some practicing educators to divert much of their professional efforts into research.

Varied Techniques Needed

The common tendency, he said, is to apply the habitually used techniques to all programs—role-playing, the buzz session, participant observation of group discussions—whatever has been successful in past meetings. Each situation must be analyzed and a method specifically selected or developed to meet the needs, he declared.

Research is needed, Dr. Derryberry said, but the work of the health education practitioner is of equal importance. Persons with native investigative ability should be enlisted for research work, while the practitioner concentrates his efforts on the translation of research findings into action and makes science contribute to the daily lives of people. "It is doubtful," he said, "if the two objectives, basic research

and health education service, can be achieved at a high level of competence by the same individual."

But beyond the hazards are challenges, Dr. Derryberry pointed out, noting that while education has always been employed to some extent in traditional public health programs, "we are now entering an era in which the health problems are such that little can be done of a preventive and palliative nature unless an effective education program gives the people an opportunity to learn their responsibilities." He mentioned as fields that are increasingly looking to educational methods, occupational health, geriatrics, hospital care, vocational rehabilitation, and civilian defense. Among the increasing calls on health educators, he emphasized particularly the challenges and responsibilities in the international health field.

Public Health Personnel Analyzed at Yale

The Yale Public Health Personnel Project, on completion, will provide information on about 6,000 items concerning individual activities, backgrounds, experiences, and working relationships of public health workers, Edward M. Cohart, M.D., of the Yale University Department of Public Health, and William R.

Willard, M.D., of the State University of New York Medical Center at Syracuse University, announced.

The acute personnel shortage, the increasing demand for new services, and the high rate of personnel turnover in the public health field were among the factors prompting this study. Financed by a research grant of the Public Health Service, it is expected to help provide a partial base for the solution of some of these problems, they said.

More than 1,000 workers in State and local health departments and visiting nurse associations have spent an average of 3 hours at two or more interviews, and about half of them have participated in time studies of 5 days or more. Some voluntary health agency employees were also interviewed through a grant provided by the National Tuberculosis Association. The study has been going on for 2½ years and tabulations and analyses are now being made, they stated.

Concerning health education, the data will provide experimental answers to the questions: What are people in public health doing in health education? What are health educators doing in public health?

"When we complete this study, we should know more about the . . . collective professional lives of health educators and other public health personnel than they do themselves," they concluded.

Nursing Home Responsibilities Of State Health Departments

Although 46 States have some statutory or regulatory provision for State supervision of nursing homes, much study and research are required in this rapidly expanding field to standardize their establishment and functions. Two papers reviewed the historical background, activities, and the many problems to be solved in nursing homes.

Nursing Homes in Illinois Licensed and Supervised

The public health nurse is an important member of the health department team concerned with the supervision of nursing homes, according to Margaret Ranck, R.N., consultant nurse, Illinois Department of Public Health. In the State health department, she explained, nurses, along with engineers or sanitarians and nutritionists, serve as resource persons and as consultants; in regional and county health departments, they make visits to the homes, give direct counseling to home owners or supervisors, and make recommendations for improvements.

Illinois Act Revised

Illinois has had statutory provision for State licensing and supervision of nursing homes since 1945, Miss Ranck noted. The act was amended in 1951, and the minimum standards, rules, and regulations set up under the act were revised in 1947 and 1952. Illustrating the techniques used in the State health department, she described the methods in obtaining the 1951 revision. Department consultants, she said, pre-

pared a rough draft of proposed revised standards. This was submitted to numerous interested groups and persons—members of the standards committee of the Illinois Association of Nursing Homes, some of the nursing homes, every full-time health department in Illinois, and Public Aid Commission social workers.

"This proved to be a slow but effective way to revise standards," she remarked. "Acceptance, both by the homes and by the health department teams, has been quite encouraging." She believes that future changes in standards should follow a similar pattern of development.

It is with the groups who wish to provide superior services and with the potential home operator that the nurse has her most satisfying experiences, Miss Ranck pointed out. After the necessary preliminary steps have been taken by the State health department and the prospective home operator, a nurse in a local health department visits the prospective home operator to answer questions and to make a tentative decision as to whether the person should be encouraged. Staff, equipment, and program of the proposed home are discussed during this visit. The nurse makes recommendations and sends the State health department an evaluation. A final visit is made by members of the local health department after the home operator makes final application.

Health Department Helps

The State health department helps to improve the care of residents of nursing homes by its work with the Illinois Association of Nursing Homes, Miss Ranck maintained. Public health nurses serve as discussion leaders, as resource persons at

meetings, and as speakers on nursing care. They are presently helping the association develop a nursing home procedure and management manual and are working with it and the University of Illinois in holding semiannual institutes on business management for nursing homes. In regard to the latter, Miss Ranck said that the large out-of-State registration for the current institute indicates the need for public health nurses in other parts of the country to help in the development of educational resources.

Standards, Ethics, Policies Needed in Nursing Homes

"At long last, we in the health field . . . are beginning to face our responsibilities in regard to nursing homes," announced Theda L. Waterman, R.N., M.P.H., executive director of the Central Agency for Chronically Ill, Milwaukee, Wis.

Miss Waterman termed the present situation "not good," and attributed it to the phenomenal increase in the number of nursing homes since World War II and to the lack of experience and preparation on the part of many operators. When most of the 14,000 homes now in existence were set up, she said, there was no one to assist the operators, to give them counseling and guidance.

The operators themselves have realized their need for standards, a code of ethics, and personnel policies, she noted. They are organizing into associations for mutual help and are looking to the nurses, in particular, for guidance and assistance.

One of the first problems that frequently arises, Miss Waterman remarked, is whether or not there should be any attempt to classify nursing homes—according to age of patients admitted, type of care required, type of disease, or financial status. She does not believe in many arbitrary classifications, pointing out that classification might neces-

sitate frequent transfer of patients from one type of home to another or might result in "labeling the patient."

Medical Care Inadequate

"In most of these homes, medical supervision is far from adequate," Miss Waterman stated. Hesitancy on the part of both the patient's family and the home operator to increase the cost of care by calling a physician, failure to recognize the need for a physician, and the frank disinterest of some physicians in cases of long-term illness were pointed out as contributing factors. "There is a need," she said, "for a more systematic and effective plan for sustained medical supervision with periodic evaluation of the patient's condition."

She noted that nursing care is excellent in some homes but cautioned especially against homes accepting patients who need types of services the home cannot give.

Rehabilitation, a service given little attention in the past, can be of real value to nursing home patients, Miss Waterman maintained. She noted that the practice of putting people to bed and keeping them there is bad for the patient and will, in time, burden society with a vast number of invalids. Rehabilitation programs, of course, can be conducted only in homes that provide adequate medical supervision and have adequate nursing personnel, she said.

Central Locations

Miss Waterman also stressed the importance of pleasant, cheerful surroundings in nursing homes and the patient's need for privacy and space in which to keep his "treasured possessions."

Concerning location, the nurse advised that homes be near good transportation, for the convenience not only of the patient's family and friends but also of the personnel. A central location will also help to insure regular visits from the physician, she added.

Business Methods and Standards In Health Administration

The success of a performance budget was reported to the health officers section of the APHA, while the Association of Business Management in Public Health was told how a joint Children's Bureau and Public Health Service account simplified procedures in one State, and how costs of validating categorical grants might be reduced. The combined State public health plan of the Children's Bureau and the Public Health Service was reported to be favored over the separate plans now in use. Performance ratings, work standards, and the function of the nonmedical administrator in public health also were discussed.

Joint CB and PHS Account Simplifies Procedures

Keeping an account which covers all Public Health Service and Children's Bureau funds allotted to Kan-

sas has saved time and simplified accounting procedures and preparation of reports for the Federal Government, Eugene W. Hiatt, business manager and attorney, Kansas State Board of Health, reported.

In addition to the one account sheet for these combined funds, the division of general services and administration keeps a sheet for each of the Public Health Service categorical funds and for funds "A" and "B" of the Children's Bureau, Mr. Hiatt stated. Also, he continued, one account sheet is set up in each division of the health department, showing the total amount of Federal funds allotted to that division, the amount and percentage of these funds which come from the Children's Bureau and from the Public Health Service, and what percentage of the total allotted to the health department by these organizations is represented by these amounts.

Each division in the health department sends to the division of general services and administration a quarterly report of the amounts expended from each fund, he said, and these reports are accumulated and sub-

mitted to the Children's Bureau and the Public Health Service.

As a result of this procedure, the speaker concluded, only one account is posted in each division, one ledger card shows the amount of funds available in the division from the Children's Bureau and Public Health Service funds, and time is saved in bookkeeping and in preparing monthly budget control reports. The State auditor and the State treasurer, who issue warrants and maintain the account balance, also benefit, since they now have only one account for Federal funds allotted to the health department instead of the eight or nine formerly kept.

Validating Categorical Funds Is Costly

Compliance with Federal reporting requirements for establishing the validity of expenditures of categorical grant-in-aid funds to States is costly in time and in money, Earl O. Wright, chief, division of administration, Ohio Department of Health, maintained.

With reduction of Federal grants to State health departments, the detailed planning of reports, evaluation schedules, and coding procedures to meet the requirements of the Federal Health Grants Manual is becoming increasingly difficult, he said. The restrictions imposed by this manual require the use of more elaborate forms than are necessary for evaluation reports and periodic summaries of activity needed by the State, he continued, and the cost of such reports should be carefully evaluated in relation to the amount of Federal grant-in-aid funds received by the State.

Ways of Reducing Costs

Mr. Wright suggested three ways of reducing the cost of validating categorical grants from the Children's Bureau and the Public Health Service: a 2-year cost accounting project to determine the actual amount of money necessary

to maintain accurate records; State budgets set up according to the State's judgment of their usefulness from the standpoint of the best interests of public health in its broad application, and allocation of grant-in-aid funds on the basis of public health results in the States; reduction of the percentage of funds prescribed by the manual for specialized expenditures and increase of the percentage allowed for supporting services.

The speaker also suggested that the Association of Business Management in Public Health formulate a plan suitable for use by all States, with minor modifications because of variation in legislative requirements, the plan to be submitted to Federal authorities for approval of its use instead of the present expensive machinery required for maintaining accurate records on expenditures of categorical funds.

Combined State Plan Favored in Field Test

In New York, 1 of 10 States in which field tests were made of the combined State public health plan of the Children's Bureau and the Public Health Service, participants almost unanimously favored this type of plan over the separate plans now in use by the two agencies. So stated Irma A. Feldstein, associate examiner of methods and procedures in the office of planning and procedures, New York State Department of Health, in reporting that State's experience with the combined plan to the Association of Business Management in Public Health.

This plan is designed "to provide in one document specific and concise descriptions of plans for public health programs," Mrs. Feldstein said. The report is to be used by the Children's Bureau and the Public Health Service in administering grants-in-aid for public health programs.

The major points which characterize the new plan now in use, the speaker said, are: (1) chapters, or titled plan schedules, designed for reporting specific public health programs; (2) the plan for executive operations, in which the commissioner of health reports his plans for the coordination of all health department activities, for new programs, for special problems and how he plans to solve them, as well as the manner in which supporting services, such as public health education, laboratory, local health services, nursing, nutrition, and statistics, contribute to the over-all operation of the department; and (3) the possibility of substituting plans of State design, provided the substitute plans include as a minimum essentially the information requested on the printed schedule.

Preparation of the Plan

Preparing the plan was a time-consuming task, Mrs. Feldstein stated. The assistant commissioners of health, their program directors, and a representative of the office of business administration reviewed the schedules. The program directors and the director of the office of business administration then conferred with representatives of the Federal Security Agency regional office. Other meetings were held by various groups and combinations of groups before the plan could be completed.

Final reports from all participants were collected, collated, and sent to the regional office, with the commissioner's plan for executive operation. Evaluation questionnaires also were sent to the regional office.

Mrs. Feldstein suggested that when this health plan is put into nation-wide operation the instructions and plan documents be sent to participants at least 5 or 6 months in advance of the return deadline. This will permit more precise planning, better coordination and clearance, more complete review, and assurance of meeting the deadline for its return, she said.

Do Performance Ratings Measure Performance?

Both supervisor and employee have a natural aversion to the service rating as a "so-called scientific measuring instrument in the highly subjective field of human relationships," Henry A. Kjentvet, B.S., director of personnel, Wisconsin State Board of Health, told the Association of Business Management in Public Health. Perhaps no other instrument for improving employee-employer relationships has provoked so much controversy, he said, pointing out that the problem is a "quarrel with form rather than substance."

Evaluation of an employee's performance should be a continuing process and not withheld from him until a specific period of time elapses, Mr. Kjentvet believes. "Formalized service ratings" should be dispensed with entirely, and any type of performance evaluation should be a "matter of importance only between the employee and his immediate supervisor," he also believes.

Noting the official and unofficial decline of ratings, Mr. Kjentvet said that personnel technicians in Wisconsin were seriously considering eliminating the legal requirement for annual employee ratings.

The Federal Government's recent overhaul of its rating system was "defeated before it was ever undertaken," he said, because of the impossibility of developing an objective rating acceptable to employees when it must "carry implied criticisms of employee effectiveness." Assuming that any individual "worthy of his hire is going to be happy over the fact that weaknesses, which he might otherwise feel free to discuss with his supervisor, are going to be made a part of an official record, represents a shocking amount of ignorance of human behaviorism," he said.

Evaluation of Manpower

Mr. Kjentvet pointed out that management has reached high tech-

nological proficiency in its system of checks and balances for evaluating "money, material, and method," but when it comes to measuring skills and individual employee achievement, it inevitably finds itself confronted with a significant area which can render all predictive efforts highly erroneous. "This is the area wherein the ideas, procedures, and techniques which have so painstakingly been developed by one group of human beings rests for their success on the manner in which they are implemented by quite another group," he said. The one basic justification of the service rating rests on its attempt to record an inventory which summarizes the capabilities and skills management has available in manpower, he stressed, but so far, today's technological advances have outstripped sociological advances.

"Individuals in a supervisory capacity who must . . . assess the aggregate of skills available to them so often lose almost completely any semblance of the objectivity which they can and do employ in other matters and render their judgment in an atmosphere of emotion," he said.

Supervisor's Dilemma

A conscientious supervisor is honestly disturbed by two difficult questions, Mr. Kjentvet stated. He must ask "What do I know about the

employee and his work?" and "What evidence is there to sustain my decision?" If he cannot answer, he must resort to some subterfuge. Also, he is frustrated by a genuine uncertainty as to whether another supervisor, in the same department and using the same employee classification, will even attempt to reach his minimum of objectivity, he added. "Thus," he said, "it may be seen that the typical supervisor in the preparation of a performance evaluation report is assailed by certain doubts which can only serve to increase his feeling of indecisiveness and can only generate ultimate antagonism toward a system which places him on the horns of a managerial dilemma."

Operating officials, too, must recognize that the possession of outstanding academic and experience qualifications does not "a priori" mean that they are good supervisors," he said. They will have to concede that despite the errors of personnel technicians, the amount of hostility which has been generated toward the introduction of any method for employee evaluation is hardly commensurate with the magnitude of such errors, he went on. And they must recognize the innate fallibility of human beings which is not "shucked off" when an individual is elevated to the role of a manager of people, he continued. Supervisors

rehabilitation—

physical
vocational
emotional

must no longer "persist in their dogged determination" that their own positions are exempt from scrutiny and evaluation on the basis that that their jobs cannot be definitely evaluated because of intangibles and long-range goals, or because "it would be degrading," Mr. Kjentvet added. "If the intangibles of a job are such as to preclude progress measurement of any sort, then it might be proper to give serious consideration to its abolition," he said.

In personnel management, Mr. Kjentvet said, "we have been all too inclined to attempt to develop our 'systems' within the provincial atmosphere of our own ivory towers," adding that although there were sound reasons, including the apathy and antagonism of operating officials, they were not sufficient to "offset the good which might have been done had we had the patience to educate not only the supervisor but the employee to the importance of mutual cooperation in the development of a sorely needed instrument for more effective management."

Richmond Notes Success With Budget Procedure

The experience of the Richmond, Va., Health Department with its performance budget shows that legislative bodies will appropriate funds for health services when needs are demonstrated and requests are substantiated by comparative service figures.

This was the conclusion reached by William R. Harton, Jr., B.S., administrative assistant in the Richmond Health Department; E. M. Holmes, Jr., M.D., M.P.H., Richmond's director of public health; and former Richmond budget officer, John A. Donaho, M.A., now budget consultant to the State of Maryland.

The Richmond performance budget shows, in both narrative and statistical form, a year-by-year comparison of the programs of work accomplished and the services performed in return for funds appropriated.

Major emphasis, they pointed out, is placed upon work programs and upon the identifiable key factors in the workload—the work units and unit costs—thus providing an opportunity to correlate the annual statistical report with the budgetary process and enabling the health department to systematically and realistically plan programs based on past experience and actual future needs. In the nursing program, for example, the total visits made and the unit cost is a more effective showing than a mere request for total operating funds to be used in purchasing so many supplies and hiring so many nurses, the officials said.

Planning Flexibility

A budget, they stated, is "a plan of work with dollar signs attached."

In the efficient conduct of a modern health department, modern budgetary and accounting systems are the effective tools of management in program planning, they said. Planning flexibility similar to the provision of contingency reserve funds by prudent management is possible with the performance budget because program activities are reviewed quarterly, they pointed out.

"A budget system which emphasizes services to be rendered rather than funds to be expended will result in a more satisfactory and effective health service to the community. This is particularly true if other essentials of a good budget system are present, which would include a modern statistical reporting system, adequate accounting procedures, and, finally, leadership by a competent executive who has a broad and thorough knowledge of the complete operations of the department," they observed.

Since the adoption of the performance budget, programs of home medical care, dental care, housing sanitation, and "acceptance of responsibility for the chronically ill" became new Richmond health services, the administrators said. Prior to the change, in the fiscal period 1947-48, the health department re-

ceived a total appropriation of \$841,728 for all services—a per capita expenditure of \$3.83. By fiscal 1952-53, the appropriation had increased to \$1,494,546, a per capita increase of \$2.66, and an appropriation increase of \$652,818 in 5 years, they reported.

Says Work Standards Are Effective Tool

Performance standards help to develop programs of personnel administration and provide a means of measuring employee performance, Charles B. Frasher, personnel consultant, Professional Examination Service, American Public Health Association, stated before the Association of Business Management in Public Health.

Mr. Frasher defined a performance standard as "that quality and quantity of output which is expected of a worker in a program of public health."

Despite reluctance to accept work standards at certain levels of employment, it is possible to measure output and to develop performance standards for professional as well as for clerical and other nonprofessional workers, the speaker continued. Also, experience has shown that fear of the probable effect on the morale of employees is apparently unfounded.

The establishment of performance standards can be approached in two ways, Mr. Frasher said. In the first, standards are set up so that each person's performance can be compared with that of other individuals doing similar work. In the second, performance expected is the same for all persons, but the past experience, education, job training, and age of each employee are taken into consideration. The latter approach, developing a performance standard for an individual rather than standards for a class of positions, deserves further consideration and probably

represents the most humane approach, he maintained.

Developing Work Standards

The first step in developing performance standards is to determine their desirability, Mr. Frasher said. A committee should then be appointed, with subcommittees representing the various professions involved; later, the lower level supervisors should join the discussions; and finally, all employees should be informed of the project. The speaker said that at some stage of the planning the method of approach should be decided on—whether to match persons against other persons or to match the individual against himself.

When plans have been completed and a decision reached as to the approach to be used, the procedures decided upon should be tested on a small group, to locate, eliminate, or improve factors which are not effective, Mr. Frasher stated. As a last step he suggested that the plan and its results be discussed with other organizations which have had similar experiences.

Administrator's Function in Public Health Noted

How the nonmedical administrator can help health specialists do a better job in public health fields was discussed by an eight-member panel conducted by the Association of Business Management in Public Health. The panel was composed of:

Thomas R. Hood, M.D., M.P.H., executive secretary, Kansas State Board of Health; Herbert R. Domke, M.D., commissioner of health, St. Louis County Health Department; Maude B. Carson, R.N., chief, bureau of nursing, Illinois State Department of Public Health; Jerome H. Svore, M.S., of the environmental sanitation services, North Dakota State Department of Health; David B. Ast, D.D.S., M.P.H., director, bureau of dental health, New York State Department of Health; Robert O. Yoho,

M.A., director, division of health education, Indiana State Board of Health; Albert E. Bailey, Ph.D., director, office of statistics and records, Pennsylvania Department of Health; Irma L. Adams, B.S., director, bureau of laboratories, Missouri Division of Health. J. W. Brower chief, section of departmental administration, Minnesota Department of Health, member of the association, served as the moderator.

Needs Broad Training

Mr. Svore, Dr. Domke, Dr. Hood, and Miss Carson joined in presenting a composite picture of the nonmedical administrator's position.

Although the designation is a negative title, the position definitely involves management duties that bring this administrator into a closer working relationship with the health officer than any other program aide. With such responsibilities, plus the fact that he frequently speaks for the agency, the training and experience of the nonmedical administrator cannot be too broad in the fields of business, public, and personnel administration. He is in the position to contribute to the betterment of over-all administration and thus aid all programs.

In Mrs. Adam's view the nonmedical administrator should take a real part in planning and coordinating activities and bring new techniques and fresh approaches to programs.

Dr. Ast emphasized that if optimum results are to be gained the administrator must know the aims of the program. He cautioned the administrator not to go to unreasonable lengths to determine what is or is not a good program but to rely to some extent on professional opinion.

Mr. Yoho felt that the administrator should remember at all times that the public health program does not exist so that the business manager can function. He emphasized that the administrator, by effectively taking part in small conferences, could indirectly be of great help in the conduct of programs.

Dr. Bailey, also stressing the participant concept, urged the administrator to recognize the need for taking people into more frequent consultation in the planning and the activities touching upon project operations.

Floor discussions centered around the use of the term "nonmedical administrator," the feeling being that the qualification is no longer essential and that such top aides should be called precisely what they are, the administrator per se. The role of the assistant to the local health officer was examined briefly and the need of his help appraised. The panel concluded that this position was rapidly coming to the fore in the team approach to the problems of public health.

Developments and Policies in Water Conservation

Progress and policies in water conservation were examined from several points of view during sessions of the APHA engineering section. From North Dakota water resource development was seen as a boon to the Nation's strength and to the health of the people. From Illinois came a plea for more extensive use of the interstate compact in the administrative approach to pollution control problems. From Pennsylvania came a warning about increasing demands by industry on usable unpolluted water.

North Dakota Planning Water Resources Uses

When the "Mighty Mo" is brought under control "in the foreseeable future," and full use is made of its waters, the Missouri River Basin will add much to the Nation's strength, in resource development and in better health for the population of the area, according to Jerome H. Svore, M.S., chief sanitary engineer of the environmental sanitation service, North Dakota State Department of Health.

Diversion of Missouri River water can be justified in large measure on the basis of sanitation and public health, Mr. Svore maintained. In some parts of North Dakota available water supplies and water for sewage dilution purposes are insufficient to meet the needs of a rapidly expanding industry, he said. Increased recognition and higher priority placed on water and sewage dilution needs for municipalities and

industry may favor diversion in these areas.

Several dams have been built throughout North Dakota to meet municipal water supply needs, to supplement river flows for pollution abatement during droughts, to provide protection, and to supplement existing water supplies, he added.

Although water needs in the State and sewage loads resulting from municipal and industrial development are comparatively small, impoundment of Missouri River water will necessitate at least primary sewage treatment, the engineer said.

Mosquito Control

Mosquito control in irrigated areas is of major concern to health officials in North Dakota, where encephalitis is apparently endemic, the speaker continued. Studies of species and numbers of mosquitoes have been conducted, as well as an education program for agencies which maintain and operate irrigation systems. In addition, cities and district health departments need assistance in planning and organizing mosquito control programs.

Water resources planning in the Missouri Basin has been greatly aided by cooperation between the Inter-Agency Committee of five governors, the engineer in charge of the Public Health Service River Basin Office in Kansas City, and other Federal agencies, Mr. Svore stated. Full utilization of the water resources of the basin will bring about industrial expansion and population growth, which will necessitate careful watching and control of water resources. As an example of future industrial activity, he pointed to the lignite deposit in the western part of North Dakota which he said has been estimated to be sufficient to supply the Nation's coal needs for 200 years.

Claims Water Pollution Best Solved By Compact

"An administrative approach to the control of interstate water resources and pollution control problems, other than through a Federal agency or one of its creation, is by means of the interstate compact," declared C. W. Klassen, chief sanitary engineer of the Illinois Department of Public Health.

He affirmed that "the States [can] realize and discharge their duties in the pollution control phase of a regional water resource plan; that they can and will [intelligently and reasonably] use this resource; and that, through interstate compacts and agreements, they will meanwhile discharge their duties and obligations to each other while still preserving their sovereignty."

Water pollution control programs should strive to serve adequately the over-all aspects of our entire economic and social environment without emphasizing one aspect to the detriment of another, he said. Waters overused for waste disposal, for example, may not adequately serve for industry, agriculture, water supply, or food sources.

Water usage is part of the foundation on which a practical program of pollution control must be based, Mr. Klassen continued. And the increasing interdependence of regional interests calls for the fitting of State programs into cooperative regional basin-resources plans.

Integration Needs

Successful integration depends upon three factors, he said—the composition, objectives, and policies of the State's control agency; the priority of water usage in the regional basin; and the type of authority exercising jurisdiction over the basin's water resources. He emphasized that full cooperation among all interested public and private groups is necessary to the success of any State or regional plan.

Mr. Klassen stressed the need for

greater uniformity among the States on industrial waste policies. He recommended that at least 45 percent of the total suspended solids be removed from all sewage and wastes discharged into intrastate waters. Sewage and wastes discharged into interstate waters, he said, should receive the degree of treatment required by applicable interstate agreements.

Since water must serve many varied facets of modern life, "we cannot hope to have an 1852 water environment and quality in a 1952 industrial development," Mr. Klassen continued. Industry, like man, must have usable water in order to survive. However, waste treatment processes often depend upon production methods. As these methods constantly change, so do the solutions to the waste problem, he said.

The States should know what industry is accomplishing in waste treatment, he said, and industry should be ever aware of regulatory requirements or policies affecting it. To be "part of the show," industry should be present "when the curtain goes up," with committees participating in the initial discussions of pollution control by regulatory agencies.

Ohio River Pact

As an example of the integration of State programs into regional, interstate agreements, Mr. Klassen cited the 1948 Ohio River Valley Water Sanitation Compact among New York, Pennsylvania, Virginia, West Virginia, Ohio, Illinois, Indiana, and Kentucky. A commission of representatives of the signatory States and the Federal government was empowered to: make pollution studies; confer with national and regional planning agencies; recommend legislation to achieve the compact objectives; and consult with industries and political subdivisions within its jurisdiction.

By majority vote of the commissioners of a majority of the States, the commission may order the abate-

ment of pollution in any signatory State—provided it is voted for by a majority of the commissioners from the State affected by the order. The latter provision maintains the State's sovereignty, said Mr. Klassen.

He felt that the Ohio River Compact was probably the greatest of this type of cooperative effort ever undertaken by so many States to solve this sort of problem.

Industrialization Presents Water Supply Problems

Industry is making alarmingly increasing demands on the decreasing supplies of usable unpolluted water in the United States, declared R. M. Helster, advanced sanitary engineer of the Pennsylvania Department of Health.

He pointed out that "the total capacity of the treatment plants operated for industrial supplies is imposing. The industrial demand," he said, "is a most important factor which contributes in many cases to the local water shortages . . . discussed so widely over the country."

Industrialization of an area brings greater needs for clean and potable water supplies, he said. Many of the Nation's water facilities are now so overtaxed that new industries are forced to develop their own supplies.

Our population, he continued, has increased 600 percent during the past century and our industrial growth has doubled in the last decade. Water use, however, has increased by several thousand percent and an even greater disproportionate increase in its use is expected in the future.

Unless control and conservation measures are instituted, he warned, the saturation point of water-using industry is not only being approached but has already arrived in some areas. He felt that the problem is particularly acute in the East North Central region of the country.

Abundance Abused

The United States has abundant ground and surface water to supply its needs, Mr. Helster continued, but all areas do not share equally in the abundance. Also, he said, two man-made problems—ground water depletion and stream pollution—aggravate the situation in most industrial areas. In Pennsylvania alone, he stated, over 2,200 miles of waterways are lost for industrial or recreational uses because of acid mine drainage.

The principal industrial user of water is steel, he said, followed by the chemical industry, petroleum products, wood pulp and paper, the coke industries, and others. Many of them have water requirements

Planning and Team Approaches To a Better Environment

The team approach to a better environment was the theme of a joint session of the APHA engineering section and the Conference of Municipal Public Health Engineers. It dealt largely with planning, and the problem was looked at in relation to city planning, with regard to the role of the health department, in terms of the contribution of long-range engineering planning, and from the viewpoint of the builder.

In other sessions of the engineers, additional problems requiring planning and appreciation of new environmental conditions were explored, including: defense area problems, use of the membrane filter in aerosol analysis, airborne contagion observations, noise as a factor in health, air pollution studies, the status of sanitary engineers, and sanitation problems of American Indians.

Health Departments Join In Urban Redevelopment

Stressing teamwork and collaborative planning, Edward R. Krumbiegel, M.D., Milwaukee health commissioner, said that the health department can contribute to the success of a "total community housing improvement program," by active participation in neighborhood conservation, rehabilitation, and redevelopment.

Practically all older urban communities are confronted with the decay or blight of certain residential neighborhoods, Dr. Krumbiegel said.

A blight elimination program embraces the protection of residential neighborhoods as yet unblighted, the large-scale improvement and modernization of moderately blighted neighborhoods, and the clearance and subsequent rebuilding of the most severely blighted areas, he pointed out.

Local development of plans for treating blighted areas is a "collaborative job," Dr. Krumbiegel noted, to be done by civic, business, labor, and neighborhood leaders in addition to the official planning agency, the schools, and such typical agencies as public welfare, health, tax enforcement, and redevelopment. The official acceptance of final plans through "appropriate local legislative action" is a necessary and vital step, he said, and collaborative planning assures that the "legislative gap between plans and operative programs will be successfully hurdled."

Role in Housing

Local health departments can contribute to better housing by appraisal of dwelling units, by the organization, education, and motivation to effective action of the citizens living in blighted areas, and by the enforcement of a housing code, Dr. Krumbiegel said.

"The health department, utilizing the personnel of its bureau or division of environmental sanitation, is the logical agency to perform the appraisal of dwellings," he said. Its contribution to effective citizen organization would be in making available "the services of health educators skilled in the techniques of community organization and group dynamics," he went on. Where neighborhood groups cannot effect voluntary correction of undesirable conditions, Dr. Krumbiegel recom-

other than volume. For instance, some may require a complete absence of hardness or solid matter while others, especially the chemical industry, need important and specific temperature qualifications in their water for cooling purposes. This requirement, he said, has led to the rapid growth of chemical industries in Kentucky, Texas, and other areas where cold water is available from underground sources, but it also has brought a rapid exhaustion of wells due to industrial overconcentration and heavy pumping.

Mr. Heister emphasized that despite the greatly increased demand for water and the fact that much of it is lost by pollution, the supply does not vary; yet our critical industrial areas may continue to expand by rigidly practicing conservation of available water resources. He recommended the recirculation of process waters, recharge of ground waters, installation of sewage and industrial waste treatment works, development of marine sources of supply through desalting processes, and construction of more multiple-purpose dams.

Progress Cited

As examples of what can be done, Mr. Heister cited, among others:

Experiments by Los Angeles County with an underground "water dam" to prevent the sea from seeping into the deep wells that supply a large part of the water for a half million people.

A reclamation project on the clogged Schuylkill River in Pennsylvania, which for more than a century had been receiving coal silt and debris from the many collieries on its watershed. All of the area's 47 collieries installed treatment works which prevent an estimated 2 million tons of silt and culm from reaching the river and its tributaries annually. Thirty-five million dollars was spent to dredge the river, 75 million dollars for sewage treatment plants, and 75 million on industrial waste treatment facilities.

mended the intervention of an official agency with police authority in the form of a housing code. "The health department is the most appropriate local official agency to enforce such a housing code," he said.

Dr. Krumbiegel recommended two basic studies in the hygiene of housing which the American Public Health Association has already made available to public health administrators: an appraisal method for measuring the quality of housing; and a proposed housing ordinance. He hoped, he said, that the APHA would undertake the development of a guide for educators who may be assigned to operational programs designed to improve the hygiene of housing.

Progressive City Planning Correlates Health Needs

Participation of health officers is indispensable in the planning of better cities, Aimé Cousineau, D.Sc., C.E., director of the Montreal city planning department, declared.

City planning is not limited to a single profession, Dr. Cousineau said, but coordinates the resources and knowledge of the engineer, the architect, the landscape architect, the sanitarian, the jurist, the economist, the demographer, and the geographer.

In Great Britain, he pointed out, the laws relating to town planning and housing have been enacted as parts of the general health laws, thereby indicating the relationship between town planning and health.

The Master Plan

Good city planning, Dr. Cousineau said, requires the cooperation of "the city officials including health officers who have a background of long and accurate knowledge of their community, the citizens' organizations, and the professional planners, whose aim is not only to design but to preserve the beauty

and the amenities of a territory as well. With the aid of these groups, planners can draw up plans or revise them conforming with the highest standards that the science of city planning is able to develop, as they always have in mind that the region, the city, the community, the neighborhood, as well as the dwelling unit, constitute the home and social life."

Dr. Cousineau pointed out that the official plan, or city map, indicates thoroughfares, open spaces, and public utility routes, and pictures present conditions, but the city's master plan is concerned with the future and indicates the trend of future development.

The master plan, he said, "is a synthesis of measures to be taken in order to solve the numerous problems pertaining to the rational planning of a city, to its extension and sometimes to its partial rebuilding. It is a means to an end."

The City Plan and Health

Some of the other statements made by the Montreal city planner relating to public health and city planning are quoted:

On public services—"There is nothing, in either the design or operation of water works and sewage plants, which precludes such architectural treatment of the buildings

and landscaping of the ground as would make the ensemble a definite asset to the community."

On growth—"Any progressive community becomes convinced that the development of its territory can no longer safely be left to take place haphazardly . . . but that such development must be planned to make the best of all opportunities to conserve the values in material wealth and beauty and to enhance public health."

On traffic—"Preventing of injury and deaths from traffic accidents is just as important and promising a field of health protection as many other fields common to the planner and the health officer."

On housing—" . . . the greatest indictment of the present civilization during the past decades was that no adequate environment for living was provided, and this matter becomes a general public concern. This indictment shall hold true in both urban and rural communities, until such time as they will be free from slums."

On zoning—"Zoning not related to a master plan and sound economic policy may cause serious losses. These ordinances must not be arbitrary, discriminatory, or unreasonable but should secure the benefit of their protective features in the conservation of property values."

On recreation—"Open spaces

radioactivity and the public's health

today
&
tomorrow

which have been found to assure health and happiness and to increase substantially the value of adjacent properties are considered an indispensable element of any city plan, and on this account health departments so concerned in the well-being of the population are always interested in their extensive development."

Home Builders Propose New Face for America

The National Association of Home Builders proposes a "New Face for America" through its six-point housing program, according to Leonard G. Haeger, Washington, D. C., the association's director of technical services and research.

Mr. Haeger described the builder's role in the team approach to a better environment, saying that the elements of good housing are good business for the home builder.

The NAHB program proposes that:

Every community require that all landlords maintain their housing to meet minimum standards of health, safety, and sanitation.

Every community launch a vigorous clean-up and paint-up program.

All dwellings found to be structurally unsafe be immediately condemned and removed in accordance with a city-wide plan.

Where entire areas of a city are found to be beyond repair, the buildings be demolished under city authority and within a complete plan for writing off the cost over a period of years through local taxation.

A direct subsidy plan be developed through local welfare agencies to help people who cannot afford to pay for proper housing. This must be done entirely on the basis of the need. The welfare agencies should insist that contributions will be made only when the family to be helped is in clean, safe, and sanitary housing.

All elements of the housing industry vigorously attack the problem

of providing lower cost housing for rent and for sale.

The above program, Mr. Haeger said, is based on builders' observations about slums: unless the profit is taken out of slum ownership, slums cannot be eliminated; low cost housing can be provided more economically by modernizing old dwellings than by building new ones; slums can't be eliminated simply by tearing down old buildings and replacing them with new ones. "Slums," he said, "result directly from neglect in keeping up the buildings and neglect in training the people."

Advise Advance Planning To Develop Fringe Areas

Many cities have found that some of the problems of fringe development can be avoided by careful advance planning and by establishing as a goal a well-ordered metropolitan community, stated Ray E. Lawrence, Black & Veatch, consulting engineers, Kansas City, Mo.

This goal can be reached, he pointed out, where the city planning commission, either acting alone or with county or township planning commissions, is able to exercise zoning control over an area extending for some distance beyond the city limits.

He suggested that a city can take the following actions toward accomplishing this goal: make a comprehensive study of existing land needs and probably also of future land needs for the populations anticipated for a reasonable period in the future; determine areas which can best be served by water, sewers, and other utilities and which are favorable for development; establish uniform subdivision regulations, including minimum lot sizes; and require all subdivision plats to be submitted to a public utility committee composed of representatives of agencies responsible for providing electric, telephone, water, and sewer service prior to approval of the plat.

He explained that annexation of fringe areas before problems of providing sewer service, refuse collection, fire protection, police protection, and other municipal services become acute is not always possible or practicable.

"The annexation of territory carries with it the obligation of providing the same municipal services which are enjoyed by the remainder of the city," he said. "To provide such services where annexations include large tracts of vacant ground between areas of development would impose a financial burden on the affected property and on the city as a whole. Also, the statutes of most States . . . involve restrictions and legal procedures which limit the extension of city limits."

Defense Areas Aided by Public Law 139

Appropriations made available in 1952 for the administration of Public Law 139 (The 1951 Defense Housing and Community Facilities and Services Act) enabled the Public Health Service for the first time to make loans or grants directly to municipalities for constructing community health facilities, reported M. Allen Pond, M.P.H., chief of the Public Health Service's Division of Engineering Resources.

Mr. Pond said that the Federal Security Agency and the Housing and Home Finance Agency, responsible for administering the act, established a joint policy committee to formulate consistent administrative policies between the two agencies. Also, he said, they make every effort to secure the fullest approval of and participation in each project by appropriate State authorities.

The act makes the Public Health Service responsible for assistance to community projects for facilities such as hospitals and health centers, water purification and sewage treatment plants, and refuse disposal facilities and services. The Housing

and Home Finance Agency assists projects for water source development, water distribution, and sewage collection.

The original Public Health Service appropriation of \$4 million did not provide for assistance to hospitals and health centers, said Mr. Pond. However, a supplemental \$4 million appropriation later permitted assistance to be granted to such facilities. The Housing and Home Finance Agency appropriations have totaled \$20,025,000.

"The program is neither to provide incentives . . . for necessary community facilities nor to compete with private lending sources," he said. "Rather it is to assist those communities which need additional facilities now and which they cannot reasonably provide without Federal financial assistance." The interest rate on such loans is generally approximate to that paid by the Federal Government itself on long-term loans, from 2.5 to 2.75 percent.

Assigns Priorities

The priorities of projects to be aided were assigned as (1) projects without which programmed defense housing could not be built; (2) projects the lack of which would not impede housing construction but without which the health of the community would be seriously jeopardized; (3) projects without which the defense program in that particular area would be appreciably delayed or impaired. Assistance to some projects had to be denied because the act prohibits the use of funds appropriated under it to meet deficiencies existing at the start of the present emergency, regardless of how desirable such projects may be from a public health viewpoint.

Loans and Grants

No funds may be made available to a community, he continued, unless it is in a "critical defense housing area," thereby having a defense plant or installation, existing or proposed; substantial in-migration; and a substantial shortage of housing and community facilities or services.

The "means test" clause of the act places upon the affected community maximum responsibility for paying for projected construction, he explained. Assistance may be given only when it is clearly evident that private borrowing would result in excessive tax or debt burdens for the community. However, determinations of communities' borrowing capacities are difficult to make, he stressed, and the joint committee felt it was not intended that a community completely exhaust its borrowing capacity before Federal financial assistance could be provided.

In some instances, said Mr. Pond, grants rather than loans may be made to municipalities with no assurances of a permanent population increase (for example, extra-cantonment areas or industrial areas with a large but short-lived impact). Otherwise, it would be literally impossible for them to provide facilities when needed, thereby seriously delaying the defense effort. Federal grants or loans on any project may not exceed that part of the facility's cost directly attributable to defense activities in the area and which are not to be recovered by the community from other sources. This limitation prevents the use of appropriated funds for correction of long standing facilities deficits, Mr. Pond explained.

As of October 1952, 208 areas had been declared critical under the provisions of the act. However, said Mr. Pond, of the approximately 70 applications to the Public Health Service for financial assistance, less than 50 came from these designated areas. Mr. Pond felt that the pressure for assistance would have been greater were it not for: (1) a general Federal policy of avoiding the development of new areas; (2) the large volume of public works construction since the end of World War II which was superimposed on the defense community facilities program of 1940-45; and (3) the comparatively sound financial condition of most American cities at the outset of hostilities in Korea.

MF Membranes Applied To Aerosol Analysis

The molecular filter membrane holds considerable promise as an effective tool for rapid and simple sanitary aerosol analysis, reported Alexander Goetz, Ph.D., professor, California Institute of Technology.

In view of the results of investigation to date, he feels that the expenditure of time and effort in a detailed study of the molecular filter's performance for airborne organisms under a large variety of

international health

today
&
tomorrow

conditions, as they may occur in the field, is justified.

The significance of the molecular filter in aerosol analysis is due to physical properties causing a unique retention mechanism which appears to be almost independent of particle size, he said. In his report, he summarized briefly these properties and their utilization. Among the points he mentioned were these: "The internal membrane structure represents . . . an extremely fine submicroscope network of great regularity, of which only the electron microscope reveals a significant detail. The structure, pore size, and so forth, can be controlled over a wide range by the production process."

"Another characteristic quality . . . is a distinct difference of the pore structure between the two surfaces of the sheet. The extent of this difference can be controlled and determines the performance of the membrane significantly. . . . The MF can thus act similarly to a two-dimensional screen, where the flow enters the filter on the side where the pore size is smallest; thus any contact between residue and filter is restricted to the top surface of the MF."

He also discussed the chemical, thermal, and optical properties of MF material and described the equipment for holding the membranes during sampling.

Experiments Described

Reviewing the work of the past 2 years in sampling and analyzing aerosols with MF membranes, Dr. Goetz described typical experiments with pure fumes and with smokes.

Commenting on these experiments, he noted that the performance of MF membranes on smokes can be less effective than on fumes as it depends upon the chemical affinity between the liquid droplets and the surface of the MF material. If the wetting between droplets and MF occurs, the former will be distributed over the inner surface of the latter and, after filling the surface capacity, may be partially redispersed by the outgoing airflow, he explained. However, for

most practical purposes, the retention is sufficiently complete, though clogging occurs sooner with smokes than with fumes.

Dr. Goetz also mentioned various field tests of aerosols through MF membranes. Contemporary with the A-bomb tests in Nevada during May and June 1952, experiments were conducted for the evaluation of radioactive atmospheric constituents, the results of which led to the decision to apply the MF instrumentation and technique used to emergency measures. Presently under way by the Air-Pollution Control Board of the City of Los Angeles is a systematic program for "smog" analysis.

Probably most important from the public health viewpoint, he pointed out, is the evaluation of performance of MF membranes with microbiological aerosols. Concluding his survey, he described examples of the work done in this particular sector, both in artificial aerosols and in the field.

Reports Limited Success In Ventilation Control

Experimental sanitary ventilation has succeeded to the extent that specified conditions of environmental control were fulfilled in control studies, reported William Firth Wells, B.S., associate professor of research in airborne infection, University of Pennsylvania School of Medicine.

Mr. Wells presented the latest 5-year review of progress in dynamic control of airborne contagion. The principle of dynamic control of airborne contagion, he said, was first demonstrated to the American Medical Association nearly a dozen years ago, and earlier, in 1932, to the American Public Health Association.

Participating in the continuing control studies are a number of hospitals, the Great Lakes Naval Training Station, the University of Pennsylvania, the New York State Health Department, the Westchester, N. Y.,

County Health Department, and the Medical Research Council of Great Britain.

Mr. Wells described some of the areas of progress:

Cross-infection was reduced when the air of the hospitals was excluded from, or purified in, operating rooms, burns units, premature wards, nurseries, or children's wards.

Contagious epidemics among school children were slowed down by sanitary ventilation experiments. An epidemic of measles among primary school children was stopped where the disease did not spread dynamically outside the school.

However, sanitary ventilation in schools did not stop infection of school children outside the schools. Where school children were exposed to carriers outside the school, colds were not stopped. Irradiation of a centralized rural school did not prevent the spread of measles through school buses. Irradiation of a village in a metropolitan area did not stop infiltration from neighboring communities.

Acute respiratory disease was a third lower where alternate barracks of a regiment of recruits at the Great Lakes Naval Training Station were irradiated. Though hospital admissions were reduced, infection of recruits quartered in the irradiated barracks by recruits from adjacent nonirradiated barracks was not entirely stopped.

Speech Interference Level May Be Clue in Noise Survey

Noise, it's agreed, can cause permanent and temporary hearing losses, interfere with necessary communication, or just disturb people, three Air Force officers reported. But noise effects below true hearing damage vary with individuals, accustomed environment, and type of sound, they indicated.

Reviewing noise as a health factor were Lt. Col. Alvin F. Meyer, Jr., MSC, deputy for environmental health engineering, Maj. Robert L.

Peterson, MSC, and Lt. Herbert B. Bell, MSC, Office of the Air Surgeon, Wright-Patterson Air Force Base, Ohio.

They reported:

The problem of precisely gauging noise effects is complicated by the widely varying adaptability of persons to noise. Individuals can and do function for long periods in noisy environments without apparent physical harm from the noise.

A community accustomed to occupations in which noise is a factor may accept high noise levels of the same general frequency characteristics. The absence of familiar noise may even be noteworthy. But the generation of sounds with a different frequency characteristic will become bothersome. A loud unexpected sound is more disturbing than expected prolonged noise. And the occasional occurrence of sound, like the drip of a water faucet, has more effect than a steady flow of water.

Noises Are Hazards

Studies conducted at nine large Air Force installations substantiate the observation that unless communication is important, noise below hearing damage levels does not reduce on-the-job efficiency. But noise that interferes with speech and understanding is definitely an occupational and health hazard. Examples are communication problems in control towers, air fields, residential areas with adjacent trains, and places in which heavy machinery is operated.

Temporary hearing loss has been reported at various noise levels. Other studies have shown gradual recovery on removal from the offending sound area. Ear plugs have aided similar recoveries. Partial recovery occurs during the time the patient is home from work, but complete recovery requires 18 to 24 hours. Hearing tests before employment and at intervals during the first few weeks or months can discover a workman's susceptibility to injury by noise. If susceptible, he

may be reassigned or required to wear ear plugs to avoid deafness.

A simplified method of interpreting the results of noise surveys in terms management and the general public can understand is needed. Speech interference level curves offer an excellent tool for engineering evaluation and can be adapted in conjunction with the total loudness of tones to give normal speech interference levels in percentages.

Air Pollution Problem Needs Long Research

"The solution of the problem of the chronic effects of air pollution on exposed populations is nowhere in sight and even the proper techniques are lacking," reported Charles R. Williams, Ph.D., of the Liberty Mutual Insurance Company, Boston.

"The main problems are those of coordination and financing," he continued. Although many, outstanding investigations are being conducted in specific related fields, he maintained there is no fully coordinated study of the health of communities having an air pollution problem. He felt that a determination of the role of atmospheric pollutions in affecting the general health of a population will require a pains-

taking and costly research for a long time.

Dr. Williams emphasized that industry is not the sole source of air contamination. The public itself is a frequent primary factor in city air pollution, he said. Automobile exhausts, burning rubbish, smoke from home heating units, and many other individual activities make each person a contributor as well as a victim. However, he felt that more valid standards for permissible levels of contamination could be developed in controlling industrial effluents.

The air pollution problem is complex and extremely confused, Dr. Williams averred. Though it has three principal effects of economic loss, injury to health, and nuisance, occurring singly or together, each problem is unique. Variations in meteorology, geography, industry and populations impede the projection of known results from one area to another. He advocated the establishment of a coordinating agency to act as a clearinghouse and to evaluate results.

Air pollution literature, he continued, is too scattered to keep abreast of all new developments. He recommended a reduced number of published journals in the field and a medium for providing an abstract service.

As a brighter aspect of the air contamination problem, he cited

TASKS FOR TOMORROW

Expansion of medical and public health research . . .

Extension and broadening of health services . . .

More health personnel effectively distributed . . .

Better health for the world's millions . . .

progress in analysis methods, resulting in more valid information about the nature of contaminants. He also called attention to advances in the agricultural phase of the problem, reporting investigations of the action of many chemicals on vegetables and livestock.

Dr. Williams felt that air pollution legislation is complicated by the fact that contamination does not stay within local, State, or even international boundaries. Many codes and ordinances prohibit atmospheric contamination in varying degrees, he said, but if some of them were enforced there would be no air pollution problem and probably very little industry. He felt that the lack of information both as to contamination measurement and the actual hazard involved stymies the formulation of practical control laws.

"Unfortunately laws are going to be necessary," he concluded. "We can only hope that the urgency of the problem will not result in bad legislation."

Sanitation Experts Help American Indians

Teams of sanitation experts are helping the American Indians to live in an environment of twentieth century sanitation, according to H. Norman Old, sanitary engineer consultant, branch of health, Bureau of Indian Affairs, Department of the Interior. The tribes have been 50 years behind in using sanitation sciences, he said, adding that a lack of public health services may be responsible.

Mr. Old portrayed a statistical picture of the American Indians' plight: The annual income of a Navajo family is less than \$400; among the Papagos of the Southwest, 25 percent of the infants born each year die within 12 months, and only 48 percent survive to the age of 18. Tuberculosis has a high incidence among all tribes.

The Indians' deplorable living conditions are due to many factors—

poor economic conditions, inadequate educational facilities, illiteracy with respect to the English language, failure to have public health education and sanitation services, and lack of organization among the numerous tribes, Mr. Old indicated. But he called for environmental improvements without awaiting the elevation of the economic status and the needed educational reforms.

A new program is under way, Mr. Old explained. Sanitary engineers, sanitarians, and public health nurses are struggling with the problems of adequate and safe domestic water supplies, excreta disposal, insect and rodent control, food sanitation, and suitable housing. Twelve young men from reservations in the greatest need of sanitation services were selected, in collaboration with the tribal councils, for training as sanitarians among their own people. At Phoenix, Ariz., they received 8 weeks of intensive training in sanitary science by the training division of the Public Health Service Communicable Disease Center. State sanitary engineers and laboratory staffs in Arizona, New Mexico, South Dakota, North Dakota, Montana, and Minnesota are cooperating in demonstration projects. Two public health education specialists are now on duty.

This year the Bureau of Indian Affairs will establish several complete public health units, each with one sanitary engineer and several sanitarians, Mr. Old reported.

Discusses Recognition Of Sanitary Engineers

The full utilization of engineers requires a high quality of engineering training, the establishment of standards high enough to bring acceptance of professional engineering skills by other professions, and initiative action by engineers themselves, asserted W. A. Hardenbergh, editor of *Public Works Magazine*.

"If a man is not an engineer, he should not fill any post requiring en-

gineering skills," Mr. Hardenbergh declared. He felt that an engineer must have completed study at an engineering school and, by suitable experience, have qualified for a license to practice engineering.

In health work, he continued, the health department head generally is not an engineer. But he needs engineering advice in analyzing present and potential problems that should be handled by the engineer, in determining their relative importance, in planning necessary measures, and in fitting this phase of the work into the over-all program. The engineer needs an adequate background for this type of planning and analysis, he said.

He urged State sanitary engineering departments to establish a division of local sanitary engineering, charged with visiting, studying, evaluating, recommending for, and assisting the activities of all local and district health departments employing or needing sanitary engineers.

To promote better community health, he said, sanitary engineers should concentrate on and anticipate the health needs of proposed subdivisions, as well as concentrating on cross-connections, industrial wastes, sewer and water extensions, water quality and new water sources, sewage treatment results, refuse collection and disposal, rodent and insect control, and home sewage disposal.

The sanitary engineer should discuss these problems fully with local health officers, as well as problems of air, shelter, civil defense and disaster planning, said Mr. Hardenbergh. He should offer complete data and recommendations for corrective measures and develop practical working plans for each.

However, Mr. Hardenbergh continued, by using the most effective methods of attack, visualizing his organization and procedures, and being able to direct the work, the engineer can demonstrate the practicability of his proposals within the limitations of available personnel and financial resources.

Standard Methods for Examination Of Dairy Products

The growing popularity of shipping milk by tank truck has presented a new challenge to milk control officials. Other developments in milk control presented to the APHA Subcommittee on Standard Methods for the Examination of Dairy Products included a recommended coliform standard count for ice cream, an adjustment in the quantity of yeast extract for the standard methods plate count of milk, and an evaluation of the direct microscopic method for determining the bacterial count of milk and cream.

Group Weighs Pro and Con Of Shipping Milk by Tank

Alerting milk control officials to the potentiality that future milk shipments may be made by tank truck—from producing farm to pasteurizing plant—Harold S. Adams, B.S., assistant professor of public health at Indiana University Medical Center, presented a preliminary report on the Committee on Milk Sanitation study of the new transport method. During 1951-52, Mr. Adams was chairman of the 10-member committee which reviewed milk sanitation practices in 27 States and the District of Columbia for the APHA engineering section.

"This system has noteworthy possibilities for improving the sanitary quality of fluid milk," he said. "It is interesting to observe that as methods of commerce and industry change, official agencies must likewise revise and reappraise their

control techniques and procedures," he commented. Now practiced most widely in west coast areas, particularly California, the bulk collection system is rapidly gaining popularity in other sections of the country, he noted.

Pros and Cons

The committee listed these advantages to bulk shipment, Mr. Adams said: Elimination of milk loss by stickage and spillage in and from milk cans; elimination of the repair and replacement of milk cans and of the hard labor necessary with the can system; improvement in milk quality because of the more rapid cooling of milk by the bulk method than by can.

Other advantages were noted: The can no longer is a possible contributor to high bacteria count. Milk producers like selling their milk in their own milk houses and can watch the sampling on their own premises. There is less misunderstanding over butterfat tests and bacterial count results.

Another advantage is that the milk company will give more attention to farm sanitation practices because rejecting a tank load is much more critical than rejecting a few cans. In California, for example, Mr. Adams said, a tanker with milk from several producers is considered a single lot at its destination. If the product is not satisfactory, the entire lot is degraded and the receiving plant or purchaser must stand the loss.

Disadvantages of the system were also noted:

From the viewpoint of the control official, more time and travel may be expended collecting milk samples. If samples from individual producers are collected, the sanitarian must

precede the tanker or ride on the truck. In the same time period, samples of milk from many more shippers can be obtained from cans at the plant receiving platform.

The system is generally practical only among producers with sufficient volume to justify installation of costly farm milk cooling and storage tanks.

Sanitation problems can arise if the tank driver is careless in handling milk transport hose or pipe and connections, or if the producer has been careless in his tank and equipment cleaning and sanitizing job.

Unless the milk company employs a well-trained hauler with prior experience in judging milk flavor or odor, milk of "off" flavor might be mixed with the milk of other producers to the detriment of the entire load.

Reports on Experiments With Milk-Free Media

To secure uniformity of results in different milk control laboratories, a dehydrated yeast extract culture medium should be used, Leon Buchbinder, Ph.D., assistant director, bureau of laboratories, New York City Department of Health, suggested in describing his latest study for the Subcommittee on Standard Methods for the Examination of Dairy Products.

Dr. Buchbinder was assisted in the study by Miss Yetta Baris, and Miss Leah Goldstein, bureau of laboratories, New York City Department of Health.

Having noted in earlier studies the relationship of the productivity of a given medium to the quantity of ingredients used, Dr. Buchbinder and his associates sought in the current study to adjust the quantity of the yeast extract used in the APHA standard methods plate count of milk closer to the present Difco standard methods T. G. E. M. medium it will replace.

Experiments were conducted with dehydrated and laboratory-prepared media on pasteurized and raw milk, and with varying concentrations of yeast extract. Comparing four different yeast concentrations in percentages of 0.35, 0.3, 0.25, and 0.20, they found that the Difco Laboratory milk-free dehydrated medium containing 0.25 percent yeast extract, 0.5 percent tryptone, 0.1 percent dextrose, and 1.5 percent agar approximated the productivity of standard methods T. G. E. M. agar more closely than the same medium with greater yeast extract concentrations.

"The concentration of yeast extract seems to be much more critical for bacteria in pasteurized milk than in raw milk," they reported. The difference was attributed to the "fact that pasteurized milk, unlike raw milk, contains bacteria which are injured but not destroyed during pasteurization and which grow in the presence of accessory food substances supplied by the yeast."

The study also assessed a new milk-free dehydrated medium prepared by the Baltimore Biological Laboratory and found it to be an adequate substitute for T. G. E. M. agar. It contains 0.9 percent milk-protein hydrolysate, 0.1 percent dextrose, and 1.5 percent agar.

Coliform Count Standard Urged for Ice Cream

Because coliform organisms in frozen desserts reveal poor sanitary practice, Leon Buchbinder, Ph.D., assistant director of the bureau of laboratories, New York City Department of Health, recommended revision of the APHA manual "Standard Methods for Examination of Dairy Products" to include a coliform standard for ice cream. At present, it only gives directions for coliform tests, he said.

Dr. Buchbinder spoke as chairman of the subcommittee for the exam-

ination of frozen desserts. He presented the findings of a collaborative study, in which United States and Canadian laboratories and dairy firms participated, to the APHA Subcommittee on Standard Methods for the Examination of Dairy Products.

The subcommittee's findings could be used as a basis for coliform standards, Dr. Buchbinder pointed out. "The present study afforded the opportunity to analyze a group of data assembled from localities distributed over this country," he said, attributing the lack of a standard to the lack of assembled data.

The subcommittee suggested a coliform standard count be set for ice cream "in the region of 10 per ml. with a provision that three of every four samples comply." Of the samples studied, 70 percent revealed a count of 10 coliform organisms or less per milliliter.

Reports on Methods

In its search for the best method of coliform analysis, the research group weighed unmelted ice cream and melted ice cream and compared the yield of organisms from each method. Analyses were also made for flavor, laboratory location, season, and culture medium. Their findings suggest that the coliform counts in ice cream are higher than those in pasteurized milk.

Six conclusions were reached:

Unmelted rather than melted ice cream is preferred for analysis. The use of undiluted ice cream was not satisfactory. The validity of coliform analysis is related to the volume analyzed; the largest quantity tested, 2 gms., gave the highest count. Sodium desoxycholate agar, the one solid medium used, gave significantly higher coliform estimates than did the one liquid medium, brilliant green bile lactose broth. Under conditions of the study, neither season of year, flavor of product, nor type of laboratory seemed to influ-

ence the number of coliforms in ice cream.

Other subcommittee members included Walter C. Bartsch, chief chemist and bacteriologist, Pioneer Ice Cream Division, Borden Co., New York City; and W. A. Cordes, National Dairy Products Co. Leo Habel, records and statistics, New York City Department of Health, performed the statistical analysis.

Stains Used in Milk Tests Rated for Efficiency

In a report on the comparative efficiency of six suggested stains for use in the direct microscopic method of determining the bacterial content of milk and cream, Nathan Mantel, B.S., of the National Institutes of Health of the Public Health Service, said that three of the stains were superior and of almost equal quality, one was slightly but significantly inferior, and two were substantially inferior.

A total of 8,352 films had to be counted in the 1951 DMC stain comparison study to obtain replicate bacterial counts from 25 samples each of raw and pasteurized milk and 4 each of raw and pasteurized cream for duplicate counts of the 6 stains by 12 participating laboratories, he said.

A completed report form for each slide counted was sent by the laboratories to Mr. Mantel for statistical analysis. The stains with the highest rank were North's aniline oil methylene blue stain, the acid, water-free methylene blue stain of Levine and Black, and the polychrome methylene blue stain of Anderson, Moehring, and Gunderson. If the average productivity of these three stains is taken as 100, then Borman's experimental stain would score 95, the Newman-Lampert No. 2 stain, 80, and Breed's 23 percent alcoholic methylene blue stain, 75, Mr. Mantel reported.

New Methods in Examination Of Water and Sewage

The following facts, among others, were reported in APHA papers dealing with laboratory and engineering aspects of water and sewage:

Progress is being made toward development of standards for rural sewage disposal systems, and better information is becoming available as to the status of present research—with one such project indicating the suitability of an activated sludge plant for an individual home.

Some of the stricter bacterial quality requirements for natural bathing water could be relaxed without detrimental effects on the health of bathers.

A new refinement in procedures for measuring the coliform population of water samples, and a new method for detecting enterococci in water are reported. Water chemists favor a new method for testing water hardness.

Sewage Disposal Systems Studied for Standards

Presenting the first report of the APHA Committee on Rural Sanitation, its chairman, John E. Kiker, Jr., M.C.E., professor of civil engineering, University of Florida, said the 1951-52 objective had been to gather factual information about progress and status of research on rural sewage disposal systems prior to establishing acceptable standards of design as its next project. Studies by health departments

and university groups are now under way.

Preparatory to the drafting of standards, the committee invited constructive assistance from persons experienced in percolation testing of soil and in supervising subsurface disposal systems. The highlights of the committee report follow:

About half of the homes built today are dependent for their sewage disposal on septic tanks and tile fields.

Where the soil is suitable, and the systems are properly designed, the septic tank-tile field method is satisfactory. It is the best available substitute for municipal sewerage and sewage treatment facilities, but it will not work satisfactorily in areas where the ground water table is high and soil conditions unfavorable. Neither will it work for very long unless the sewage is properly conditioned for subsurface disposal—a function of the septic tank, which must be properly designed for the purpose.

Septic Tanks

Present studies favor a two-compartment septic tank, either of equal compartments or with about two-thirds of the total capacity in the first compartment. It should not be inferred that a well-designed single compartment tank of ample capacity will not give good performance. None of the results to date justify a radical departure from present health department practice. Unless changes would have a marked advantage over present practices, they would only serve to confuse the average builder and add to the worries of the already overburdened sanitarian.

Capacity of septic tanks should be increased by 50 percent when home garbage grinders are used. Absorption fields should be increased by an

equal amount to allow for an increased tendency of sewage containing ground garbage to cause clogging of the soil. There is no evidence that absorption field areas need be increased because of household detergents.

Results of research to date indicate that multiple percolation tests should always be made to determine the absorption characteristics of soil in which tile fields are to be placed. Tests should be continued until soil is saturated and percolation rates are consistent. Standardization and agreement are needed on the size of test holes because of the wide variation in water consumption, but there is doubt as to the feasibility of meticulous refinements of the percolation tests.

Sewage Disposal Plant Can Be Used in Home

A small activated sludge plant has been demonstrated to be suitable for sewage disposal in individual homes, reported Don E. Bloodgood, C.E., professor of sanitary engineering, Purdue University.

Recognizing the need for improved single-home sewage disposal facilities, particularly in rural areas, he explained, a research project was carried out at Purdue University to determine whether the aerobic process might be feasible. The quality of the effluent and the quantity of sludge produced were two of the factors investigated.

Testing was divided into three periods. During the first—399 days—a grinder toilet, compressed air aeration, and fresh water for flushing were used. During the second—100 days—the grinder toilet was replaced with a standard flush toilet. During the third—137 days—a grinder toilet was again used; the effluent, however, was recirculated for toilet flushing, and aeration was accomplished either by compressed air or by admission of air into the recirculation pump suction or discharge.

Treatment Unit

The treatment unit, Mr. Bloodgood stated, was a 227-gallon rectangular metal tank divided into an aeration and a settling compartment. Compressed air was supplied by a diaphragm compressor designed for spraying paint and was applied through a standard carborundum diffuser tube. During the first and second testing periods, the effluent was removed from the sedimentation compartment by a weir made of a split 4-inch pipe and discharged to a floor drain. When the grinder toilet was used, the sewer line leading to the treatment tank was a 1-inch galvanized iron pipe; for the standard toilet, it was a 4-inch pipe.

He reported in detail the data collected on the number of usages, water consumption per use, toilet paper used, pH of the aeration tank, dissolved oxygen, and suspended solids and BOD of the effluent. The mixed liquor solids were not removed until the end of the first month of the second period, when the concentration had built up to 12,000 ppm, he said. At this time, 17 gallons of sludge were siphoned into 10-gallon containers, which remained in the basement where the tank was located. Never at any time did offensive odors develop in the system, Mr. Bloodgood noted.

Small Plant Feasible

From this study, he concluded that:

A small activated sludge plant can be made to operate continuously without odors for 399 days with the production of a satisfactory effluent and without removal of any solids except those going out in the effluent.

Although the minimum size for a tank to serve a family has not been determined, the indications are that a 227-gallon tank is large enough for a family of three.

Grinding the fecal matter and toilet paper is necessary prior to discharge to the aeration unit.

The effluent can be recirculated for toilet flushing without harming the process.

Controls Could Be Relaxed On Bathing Water Quality

"Admitting the difficulties of conducting studies in which nature rather than man controls many of the variables, sufficient evidence is available to indicate that some of the strictest bacterial quality requirements for natural bathing water now existent might be relaxed without significant detrimental effect on the health of the bathers," declared Albert H. Stevenson, M.S.

Mr. Stevenson, deputy officer in charge, Environmental Health Center, Public Health Service, reported on three studies of natural bathing waters and the population groups using them.

The studies, he said, were conducted on (1) two Chicago beaches on Lake Michigan; (2) the Ohio River at Dayton, Ky., and a fresh water recirculation pool in the same area; and (3) the beaches at New Rochelle and Mamaroneck, N. Y., on Long Island Sound. Families in these areas were furnished a calendar record form on which they recorded daily swimming and illness experience. Water quality determinations were made on samples collected from the selected swimming areas at intervals necessary to observe significant fluctuations.

Illness Incidence

Mr. Stevenson, summarizing the results of these studies, pointed out that:

In virtually every instance the illness incidence among swimmers was higher than that among nonswimmers (those not going swimming during the study), an expected finding inasmuch as water is an abnormal habitat for man regardless of its bacterial quality.

In the comparison of illness incidence among swimmers with that among nonswimmers, no significant correlation was observed which could be attributed to swimming in natural waters of different quality at the areas studied.

Illness incidence among swimmers under 10 years of age was some 100 percent higher than for those over 10 years of age.

More than half of the illnesses among swimmers were eye, ear, nose, and throat ailments; about one-fifth were gastrointestinal disturbances; and the remainder were skin irritations and other illnesses.

Specific correlations between illness incidence and bathing in waters of a particular bacterial quality were observed in two instances. In one, a significant increase in illness incidence was observed among swimmers when the water had an average coliform content of 2,300 organisms per 100 ml. over the illness incidence when the average coliform content was 43 per 100 ml. The observed increase could occur as a result of chance but once in 50 trials, Mr. Stevenson said. This evidence, however, should not be taken as conclusive, he warned, since only 3 days were selected for study in each instance.

The second instance of positive correlation was observed in the Ohio River study where it was shown that, despite a relatively low incidence of gastrointestinal disturbances, river swimming water having a median coliform density of 2,700 per 100 ml. appears to have caused a significant increase in such illnesses among swimmers. This result, he noted, must also be treated with great caution because of the small number of cases involved.

Report on Reliability of Coliform MPN Methods

Regardless of cause, variations due to changes in the coliform population of water samples may be accurately measured and the variation due to proper laboratory practice can be measured and controlled by the use of procedures reported by Ralph E. Noble and Marjorie L. Sutherland, Ph.D.

Mr. Noble is the principal filtration bacteriologist of the Chicago Department of Public Works. Dr. Sutherland is a biostatistician with the Illinois Institute of Technology, Chicago. In their studies on reliability of coliform MPN (most probable number) indexes, they combined the standard procedures of statistical analysis variance and the MPN method of estimating coliform population.

Using this method for their calculations, it may be possible for bacteriologists to "have more confidence in their data," they said. They reported that their method makes it possible to check and compare the accuracy of data from different laboratories and that it is also possible to realize that unusual fluctuations in coliform indexes may be due to real causes other than laboratory techniques and to determine the characteristics of the environmental influences which cause these fluctuations.

Methods Used

Using duplicate MPN determinations from the same source is essential to the procedure advocated by the Chicago scientists. Four master samples were collected daily for 25 days, one pair in the morning and one pair in the afternoon, they said.

Questions of accuracy and precision, or "how closely does an MPN approximate the true coliform level of the source," and "how reproducible are the MPN's regardless of their accuracy," must be answered in interpretation of an MPN, the researchers postulated.

As an example, they cited: "Assume the coliform level of a source is 20 per 100 ml. and duplicate MPN's are 17 and 23. A second pair gives 6.8 and 13. The precision is about the same in both cases but the accuracy differs. In the first case the average is identical with the true coliform level, while in the second it is 10 less. Any feature of the method likely to cause a loss or gain of coliform organisms, such as improper storage of samples, would

bias the accuracy of the MPN but might not affect the precision."

In their experiments, a statistical quality control chart for ranges was used to measure the general quality of laboratory technique. They found variation due to laboratory technique to be relatively uniform even though the source population level fluctuated from day to day. Analysis of variance was used to measure the variation characteristic of laboratory replicates from one sample, source replicates, morning and afternoon samples, and samples taken from day to day. They reported that information regarding the variances at these sampling levels can be used as the basis for experimental plans designed to increase the sensitivity of tests in coliform population studies.

New Method Detects Enterococci in Water

A new method for the detection of enterococci in water was presented by Warren Litksy, Ph.D., assistant professor of bacteriology, University of Massachusetts, W. L. Mallmann, Ph.D., professor of bacteriology and public health, Michigan State College, and C. W. Field, M.S., Michigan State College.

They explained the two-step procedure as: (1) a presumptive test in a selective enrichment and (2) a confirmatory test in a selective diagnostic medium. The presumptive test is made by planting suitable dilution of the test material in dextrose azide broth (Rothe) for 48 hours at 37° C. Several loopfuls from positive tubes are transplanted to tubes of the new medium, ethyl violet azide broth, which are incubated at 37° C. for 48 hours. Growth in the latter medium is reported as a confirmed positive test for enterococci. *Streptococcus faecalis*, *Streptococcus zymogenes*, *Streptococcus durans*, and *Streptococcus liquefaciens* grow equally well in both media. The media in a series of comparative tests on river water gave a hundred-fold to a thousandfold more entero-

cocci than did either SF broth at 45° C. or Winter-Sandholzer media.

Many Chemists Favor New Water Hardness Test

A great majority of water chemists favor the adoption of some form of the Schwarzenbach method for determining hardness in water as one of the standard tests, according to James E. O'Brien, B.S., senior sanitary chemist, division of laboratories and research, New York State Department of Health.

Mr. O'Brien called the Schwarzenbach method, published in 1946, "vastly superior" to the four methods now listed in the "Standard Methods for the Examination of Water and Sewage." He noted that a committee operating under the American Water Works Association general committee E-5-9 has recently reviewed all the water hardness methods known.

If the committee will recommend either of the Schwarzenbach titrations for inclusion in the 10th edition of Standard Methods is not known, he said, adding that "it is a foregone conclusion" that it will recommend dropping one or more of the methods now listed.

The reagent used in the Schwarzenbach method is the disodium salt of ethylenediaminetetraacetic acid commonly marketed in this country under the trade names Versene or Sequestrene. This chemical is a sequestering agent which holds the calcium and magnesium in solution in a form known as "chelation." "The Schwarzenbach titrations are very precise," the chemist said, "and calcium and magnesium may be determined with a high degree of accuracy provided that certain well-established precautions are observed."

Describing the three known factors which influence the results of this test, he reported that two variations of the original technique have been proposed, both of which have their champions.

School Health Service Trends And Research Studies

Research in school health was the topic of joint sessions of the APHA sections on dental health, food and nutrition, and school health with the American School Health Association. The session heard a report on trends in school health services since 1940, a call for standardizing school health examinations of teachers, a statement that immediate application of preventive measures is a practicable approach to child dental health, a claim that education pays in nutrition, and an account of narcotic problems among adolescents.

Fluoridation Would Help Ease Dental Demands

Immediate application of preventive measures such as fluoridation of public water supplies was urged as a practical approach toward the solution of child dental care problems by George E. Waterman, D.D.S., assistant chief of the Division of Dental Public Health, Public Health Service.

Clinical care alone cannot solve the child dental care problem, Dr. Waterman stated in reporting the preliminary results of a 5-year study completed last year in Richmond, Ind. The study, Dr. Waterman indicated, shows:

There are not enough dentists to care for the backlog of dental defects among the Nation's school children.

Effective work on the part of dental assistants can reduce substantially the workload of dentists.

A vast majority of school children do not get adequate dental care; only 25 percent of those participating in

the program had prior dental attention other than emergency treatment.

The convenience of dental care facilities is a factor in the success of a community dental program.

It takes three to five times as much time and effort to care for the lifetime accumulation of dental needs as it does to cope with these needs on a year-to-year basis.

Timely fillings can save a large percentage of teeth, and adequate care throughout childhood might eliminate most needs for extraction.

The project for care of the Richmond school children in the 16 school clinics was developed by school officials, the Indiana State Board of Health, and the Public Health Service, Dr. Waterman said, stressing that enthusiastic support was given by the local government, the school board, the dental society, and the general public.

Health Services in Schools Show Marked Growth

The number of school systems having health services has increased considerably since 1940, H. F. Kilander, Ph.D., specialist for health education, Office of Education, asserted.

Dr. Kilander reported that:

Ninety-one percent of the school systems in cities with a population of 2,500 and over now have a school health service which includes at least a medical examination and a dental examination.

Physicians are available in 63 percent of the school systems; nurses, in 85 percent; dentists, in 40 percent; dental hygienists, in 16 percent; other health personnel, in 12 percent.

The administrative authority for the school health service program, reported by 2,856 city school systems, is as follows: board of education, 60 percent; board of health, 11 percent; both the boards of education and health, 23 percent; other authority, 6 percent.

The school health service is financed by the board of education in 55 percent of the school systems; by the board of health in 10 percent; by joint financing of the two in 23 percent; and by other authority in 12 percent.

Although the school health program is still predominantly administered and financed by boards of education, there is a slight but definite trend toward joint administration and financing, he said.

Achieve Better Food Habits With Nutrition Education

Given education in nutrition, most elementary school children will form better food habits than eighth graders and high school students, according to Floy Eugenia Whitehead, Sc.D., director of nutrition for the Wheat Flour Institute in Chicago.

Dr. Whitehead referred to the parish-wide diet studies of school children in Ascension Parish, La. These were started in 1944. Records of grades 2 through 11 were used, but no attempt was made to follow the same group of children from year to year, or from grade to grade. All schools in the parish were included.

The speaker reported that an appraisal of food habits made in 1944 revealed the parish school children were not as well fed as they might be. For only 1.6 percent of the pupils could food habits be called "good." Rated "fair" were 59.5 percent. Considered "poor" as to food habits were 38.9 percent.

To illustrate the progressive improvement in diets, Dr. Whitehead presented annual data on the percentage of children with poor diet habits in each grade.

As an example—not more than 5 percent, and often much less, of the youngsters in grades 2, 3, 4, 5, 6, and 7 had faulty diets in 1950. For 1944, in the corresponding grades, the number of children with poor diets ranged between 24 and 44 percent. In the higher grades—8 through 11—the boys and girls with poor diets included between 36 and 49 percent of the students. The percentages varied from grade to grade. But 6 years later, in 1950, the number with poor food habits had dropped to between 6 and 15 percent of the eighth grade and high school students.

Nutrition Education

Nutrition education was planned and put into action by teacher committees who coordinated classroom activities and school lunch programs. Outside assistance came from parish educational leaders and community agencies. Consultants on home economics, health, and education assisted. A full-time nutritionist worked for the first 4 years and returned to evaluate results in 1950-51.

Dr. Whitehead believes that the diet improvements were due to real changes in food habits. "It may be," she remarked, "that during the year children learned which foods were highly protective and that this improvement reflects increased knowledge rather than improved practice."

Consistency in practice was found, however, Dr. Whitehead continued, by comparing diet records with school lunch records. Improvement was indicated by physicians' examinations and by laboratory tests of blood plasma taken from a representative group of high school girls.

The effectiveness of the school nutrition program can be seen in a study Dr. Whitehead mentioned of comparative intakes of food groups. The study, based on standards of recommended dietary allowances, was made in 1947-48 and repeated in 1950-51. It included not only Ascension Parish but nearby St. Martin Parish, where no unusual nu-

trition program had been conducted. Improvement in diets over 1944-50 would be expected as the result of improved economic conditions. Therefore, it was necessary to look at the food habits of children in a comparable situation. Food habits were found to be significantly better in Ascension, yet potential food expenditures were not as high there as in St. Martin during the years of the study.

"If economics alone were the dominant force affecting food habits, one would expect better diets in St. Martin than in Ascension," Dr. Whitehead concluded. "The dominant force affecting improved food in Ascension Parish from 1944-51 was the educational program."

Health of the Teacher Main Factor in Schools

The mental health of the teacher is the most important single factor in the classroom environment, maintained Morey R. Fields, Ed.D., director, bureau of public health education, New York City Department of Health, in his discussion of healthful living in schools.

"The school cannot provide environmental experiences which will contribute to desirable development unless it is staffed with healthy teachers," Dr. Fields stated. "From a negative viewpoint, the unstable teacher exerts such a detrimental impact on children that she should not be allowed to remain in contact with them."

"Effective guidance of children is successful to the degree that it is participated in by teachers with well-adjusted and wholesome personalities," he said, adding that silently, insistently, the dress, carriage, neatness, voice, manner, and habits of the teacher are influencing the lives of the children. No school health impact is likely to be stronger than that of the teacher, for children often learn from daily experience with that teacher.

He listed as other considerations in providing a healthful school environment: position of buildings; size, temperature, humidity, ventilation, lighting, and seating of classrooms; cleanliness; safety of the hallways and stairs; drinking and handwashing facilities; toilet facilities; and sufficient and safe play areas—factors for which standards are available from reliable sources and which can usually be adequately controlled.

"Factors related to human understanding, however, will not respond to laws, sanitary codes, or the architect's drawing boards," he emphasized. "Here, controls are personal, from the mind and the heart," he concluded pointing to areas of bigotry and prejudice permitted to be taught in many schoolrooms.

Adolescent Drug Users Ignorant of Dangers

New York City adolescent drug users in 1950 knew how and where to obtain drugs but were "woefully ignorant" of their ill effects, said Harold Jacobziner, M.D., director of the bureau of child health, New York City Department of Health.

Dr. Jacobziner referred to the rise in narcotic usage among the school age population which reached its peak in May 1951. Between September 1950 and February 1952, the city's school health service uncovered 167 cases requiring treatment. These represented about one-fourth of the drug users in the schools, according to Dr. Jacobziner.

The largest number of users was found among the 16-year-olds, he said, and the rate of narcotic usage was much higher in vocational than in academic high schools.

"Though every racial, ethnic, socioeconomic group and creed was represented, there was a marked concentration in critical areas inhabited by individuals or groups subjected to many deprivations and discriminations, and many came from disrupted and disharmonious homes," he noted.

Narcotic users are in part the products of an unhealthy and unhappy environment so that total treatment of addiction calls for understanding the underlying causes and motivations of addiction, he said. Total treatment, he indicated, would not be limited to medical treatment and follow-up but should aim at the rehabilitation and re-education of the user in a drug-free environment, with full preparation for his return to his former environment. One effective way of preventing the psychological ills leading to addiction lies in a comprehensive program of slum clearance, good sanitation, good nutrition, good housing, and good parent-child relationship, bolstered by a program of good physical and mental health, he added.

Standards Should Replace Examination Variables

Standardized procedures of examining and recording should be developed wherever school health examinations are made by both private and school physicians.

Renée Zindwer, M.D., chief of the bureau of maternal and child health, New Jersey State Health Department, evaluated the method, content, and results of routine health examinations given teachers in the Nashville, Tenn., public schools.

From a survey of 843 Nashville teachers examined by both school and private physicians in 1948, Dr. Zindwer concluded that there were "definite inadequacies in the content of the physical examination," adding that the examining physicians should be informed about the exact purpose and use of the examination and that a close relationship should be maintained with the school service staff.

Annual Examination

Dr. Zindwer suggested that the differences she noted in recording might be due to interpretation—

many private physicians might not have considered corrected vision or artificial dentures to be defects. Some differences might be due to emphasis—for example, school physicians found significantly more emotionally disturbed people, she reported.

Nashville teachers must have a medical examination every summer. Teachers under civil service may be examined at their own expense by a private physician or without cost by the school physician. Teachers not having civil service status must be examined by the school physician. About two-thirds of all teachers had civil service status in 1948.

Dr. Zindwer remarked that "although two-thirds of the teachers had the privilege of choosing their private physician for the examination, only one-fifth actually did so." One motivating factor, she suggested, was expense, "particularly among the older teachers." Many of these still considered the examination as something to submit to exclusively for the convenience of the board of education without recognizing the intrinsic value to themselves. In other instances, she noted, "the examination by a school physician was preferred because of friendly relationships and because the teachers liked to discuss their health problems with the school doctor."

Examination Items

Medical and related information was grouped around 17 items on the routine examination, to include:

Eyes, dental, obesity, cardiovascular, respiratory, orthopedic, gastrointestinal, genitourinary, fractures, major surgery, minor surgery, emotional, tumors, miscellaneous, multiple findings, free, recommendations.

Some of the items, according to Dr. Zindwer, included actual defects predominant at the time of the examination; others were weighted with items of medical history. "Miscellaneous" included a variety of findings not falling into the examination grouping, as—history of dia-

betes, rheumatic fever, allergy, or of multiple miscarriages. For all ages, 12.5 percent of the 843 teachers examined were found to be "free"—without any significant history of disease and showing no defect.

Sex distribution of findings indicated that women had significantly more eye defects, cardiovascular difficulties, operations, and multiple findings than the men teachers, Dr. Zindwer said.

To compare the findings of school physicians and private physicians, Dr. Zindwer explained, "we considered only the teachers with civil service status in order to have a more homogeneous group. Of the 562 people in this category, 148 were examined by private physicians and 414 by school physicians."

Emotional Disturbances

"The higher incidence of eye defects, dental defects, orthopedic problems, and miscellaneous findings as well as of recommendations noted among those examined by school physicians," she continued, "was highly significant and so was the fact that the group examined by private physicians had about three times as many people free from defects or pertinent history as those examined by school doctors. The private physicians also found significantly less emotional difficulties. Altogether, the private physicians' records showed 1.7 positive findings per person, whereas the school physicians noted 2.6 findings per person."

Dr. Zindwer urged that consultant services and special examinations be made available when the routine examination indicates the need for further studies, and that more attention be given to the "importance of detecting and evaluating" emotional disturbances among teachers than is possible through a routine health examination. "We must find a practical method for screening such cases and referring them to specialists for further study and recommendations," she stated.

Studies and Programs In Dental Public Health

Several facets of dental public health received consideration at meetings of the dental health section. The dental care program in New York for the rehabilitation of children physically handicapped; a public program in Rhode Island supported by a private institution, government agencies, and private endowment; the patient-dentist relationship; and the improvement of the status of dental public health were among the topics discussed.

New York Dental Program Treats Malocclusions

Administering the dental rehabilitation program for handicapped children in New York State still presents problems, even after the establishment of apparently sound procedures, observed Arthur Bushel, D.D.S., M.P.H., and David B. Ast, D.D.S., M.P.H., assistant director and director, respectively, of the bureau of dental health, New York State Health Department.

"There is the occasional orthodontist who does not agree with the department's decision as to eligibility of a case, the rejected applicant who feels he is being discriminated against in his request for inclusion in the specialist roster, the judge who suddenly cuts off funds so that even cases which have been under treatment are not approved for essential, continued care. There's the occasional study model broken in shipment, and the child who proves completely uncooperative and for whom care must be discontinued," they said.

One indication of success, they reported, is that almost every qualified orthodontist in upstate New York has asked to participate. The cur-

rent roster of approved orthodontists includes 100 in New York City and 96 in upstate New York. The current caseload of about 1,500 for the entire State represents rapid expansion of the program. Applicants in upstate New York rose from 51 in 1946 to 442 for the first half of 1952, and 54 percent of the upstate cases reviewed in that period were approved for rehabilitation.

Procedures

Continuing their description of the program, they reported that:

Although physically handicapping malocclusion came within the legal provisions of the State aid rehabilitation program, it wasn't until 1945 that a separate orthodontic care program for children was initiated under the bureau of dental health. An advisory committee was appointed to determine, among other functions, fee scales, qualifications of orthodontists, and classification of handicapping malocclusions.

The committee early realized that it could not be too precise in defining handicapping malocclusions because of the infinite number of variations possible and because of the difficulty in evaluating the psychological and physical factors which create a physical handicap. Drs. Bushel and Ast explained. Despite these difficulties, it established the following classifications of malocclusion as to a guide to eligibility:

1. Malocclusions associated with cleft palate, cleft lip, or ankylosis of the temporomandibular articulation.

2. Malocclusions resulting from severe structural deformities involving growth and development of the mandible and/or maxillae: prognathism, retrusion, micro- or macrodevelopment of the jaws.

3. Severe malocclusions resulting from disease or trauma of the mandible and/or maxillae.

4. Malocclusions resulting in disfigurement or speech defects which may present a serious obstacle to normal development, education, and employment of the patient in later life.

Alerted case finders refer detected cases to the local health officer who authorizes consultation with any licensed dentist of the parents' choice. If the case qualifies for rehabilitation, the dentist sends the required diagnostic aids—mounted dental X-rays, full set of study casts, and profile and full-face photographs—along with his written report to the dental bureau for review.

Fees

Under existing State law, the children's courts determine the degree of financial eligibility of applicants for rehabilitation. The State health department has jurisdiction over all professional phases of the program. The county and the State each contributes 50 percent for that part of the care borne by public funds. The local health officer assists the parents in petitioning the children's court for care. Care may be provided only by orthodontic specialists on the health department's roster. No more than 1 year of treatment may be authorized at a time, but up to 3 years may be approved. Usually more than 1 year of treatment is required—the average has been 1.9 years, they reported.

The maximum fee for the first year's treatment is \$300 for service in the orthodontist's office, or \$200 at an approved clinic. Near the end of a year's treatment, the orthodontist submits a progress report to aid the courts in determining if continued care is to be ordered. The maximum fee for each of the second and third years is \$200 for private orthodontists and \$120 for approved clinics. Additional retention care is available at not more than \$5 a visit for a maximum of 12 visits. In all, a maximum of \$700 may be approved for active treatment.

In 1951, 1,105 children received care costing \$246,673 at an average cost of \$223.

Extent of Program

Some of the malocclusion cases require other services such as fillings, extractions, dentures, and obturators, for complete rehabilitation of the mouth. Speech therapy, particularly for cleft palate cases, is obtainable. Children requiring full dentures, extensive partial dentures, or other extraordinary dental service to correct a physical handicap are eligible under the program. The Veterans Administration fee scale is the guide for such general dental services, and any State-licensed dentist is eligible.

It is apparent, Drs. Bushel and Ast believe, that orthodontists serving under the program are "extremely conscientious and certainly are not attempting to prolong the period of care."

Facial Orthometer Is Used To Assess Malocclusions

The facial orthometer, an instrument devised to measure quantitatively the dentofacial morphology of population groups, was recommended as an epidemiological tool for the study of malocclusions by Walter J. Pelton, D.D.S., chief, Division of Dental Resources, Public Health Service, and William A. Elsasser, D.D.S., a member of the division's staff.

This instrument, they said, permits accurate classification, measurement, and controlled experimentation. It may be used to establish the "ideal" dentofacial pattern and also to detect the various deviations from this pattern.

They explained that the term "ideal" is used for the theoretical face whose dentofacial index (DFI) would not only be 0 but whose every measurement would be exactly the same as the standard average for each measurement taken. "Normal" represents the face whose measurements fall within a standard range of the "ideal."

Dentofacial Index

The dentofacial index, they stated, consists of the summation of the weighting of seven separate components. It is thus an expression of the additive effect of several individual variables. To establish the orthometric standard of "norm," the mean and standard deviation for each of five components were determined by observations on 93 "normal" white children, aged 6 through 12 years.

The components which make up the index make possible a quantitative method of classifying malocclusions, they stated. The index provides a useful measuring device suitable for studies of the epidemiology of dentofacial deformities.

When investigations of the incidence and prevalence of malocclusion are carried out on a wide enough scale, a valid concept of the nature and extent of the aberration will be had for the first time, they said. Only through such studies can knowledge be gained as to the effect of various environmental influences on malocclusions.

Finally, they stated, the dentofacial index lends itself readily to use for basic studies of the effects of growth and development upon the face as well as for measuring the changes brought about by treatment.

Combined Resources Used In Dental Care Program

A program for dental care of children combining the resources of separate but cooperating organizations—a private institution, agencies of Federal, State, and local governments, and private endowment, was described by Alfred F. Morin, D.M.D., the director of the Joseph Samuels Dental Clinic, Rhode Island Hospital, Providence.

The Rhode Island Hospital, a private institution, supplies the physical accommodations for treatment, Dr. Morin said. The cost of dental care

is divided among the patients, the deficit being absorbed by the hospital and the clinic endowment fund. As a result many receive proper treatment without the stigma of having been forced to accept charity.

This subsidized plan, offering families of moderate means dental treatment for their children at small fees, is one phase of the program, Dr. Morin stated. A second phase is the treatment of preschool-age children and education of their parents in the importance of dental health, with funds provided by Federal and State agencies on a fixed cost per visit basis. Provision for dental care of children on welfare rolls is a third phase of the program, financed by city welfare departments, the clinic endowment fund, and the hospital.

The Joseph Samuels Dental Clinic, founded in 1930, in addition to providing community services, has become a center for training dentists in the care of the child population of Rhode Island. Although the program is not the panacea for all dental problems, Dr. Morin believes that dental treatment for children approached from a group basis and formulated into one program with maximum use of existing facilities benefits all participants.

Sociodramas Can Show Stresses of Dental Patients

An understanding of emotional factors, acquired through "role-playing" devices, may help public health and private dentists with human relations problems, William G. Hollister, M.D., M.P.H., mental health consultant of the Public Health Service, believes.

Emotional reactions prevent many persons from receiving needed dental care and, at times, block effective development of public dental programs, Dr. Hollister said.

Dentists, he reported, have requested help in understanding "problem patients," in dealing with the

public's general fear of dentistry, and in getting people to accept and follow through on dental procedures.

From field observations, Dr. Hollister found that most dentists are prepared to educate or to convince by argument. But many of them do not understand how to work with the patient on an emotional level, he said.

Dr. Hollister named as the learning goal the comprehension of the way one's own feeling and the other person's feeling affect a relationship. Pertinent psychological knowledge and enactment of experiences, condensed into a brief workshop or trainee course, can provide this understanding, he said. To illustrate, he outlined a course of this type.

Laying the foundation is a lecture and chalk talk which covers briefly the role of emotional growth in personality development, the component parts of personality, and the physiological basis of emotions. From this material the trainee develops a concept of the basic emotional needs of the individual and how these needs motivate and color behavior.

Reveals Feelings of Both

Through a series of role-playing devices, the trainees experience the "feelings" involved in a dentist-patient relationship. A member of the group, in the role of a dentist, silently approaches a "patient" in a dental chair. And the other members of the group portray their reactions to this "dentist." Thus, they become aware that the role-player, without words, has transmitted to them certain feelings. Through discussion, the group can explore how this nonverbal communication of feelings affects the patient's confidence in his dentist, and the professional person is aided in diagnosing the "feeling problem" with which he is confronted.

Similar "experience techniques" are used to study the effect of the patient's expectations on the relationship, how the "counter-feelings" of the dentist toward the patient

complicate his relationships, and the effect of personality qualities, such as a dentist's warmth and noncritical attitude.

Actual problem situations from the dentist's daily work with people are enacted in sociodramas and discussed. Here the dentist gets practice in working with anxiety, fear, and resistance in a patient before he actually meets the situation. He not only works out the "words" needed, but by experience he begins to sense the attitudes in himself that are basic to better relationships with others.

Improved Dental Status Seen in Proposals

A twofold proposal for securing a better understanding of the objectives of dental public health and, incidentally, improvement in the administrative status of dental units in State health departments was offered by W. Philip Phair, D.D.S., M.P.H., assistant secretary of the Council on Dental Health, American Dental Association.

As the first part of the proposal, Dr. Phair suggested several ways in which dental health directors can help promote this understanding: Foster local cooperative arrangements between dentists and other health professions through joint society meetings and community health work; help in teaching courses in dental public health in schools of dentistry, medicine, and public health; participate actively in health department in-service training programs; demonstrate a genuine interest and good knowledge of other aspects of public health work; write their ideas of what a comprehensive dental health program in their area could be and work energetically and systematically toward achieving it; inaugurate convincing demonstration programs; measure and publicize the effectiveness of their activities.

State Conferences

He recommended, as the second part of the proposal, exploring the possibility of State conferences. "In States where the problem seems immediate enough to warrant specific action," he said, "dental societies could sponsor an all-day conference with participants representing dentistry, medicine, and public health within the State. The conference might also be able to obtain assistance from management consultants, schools of public health, representatives from one or more national organizations, such as the American Dental Association, the American Public Health Association, and representatives of the Public Health Service."

Listed as possible objectives of such a conference were these points: Help acquaint participants with dental needs and resources in the State and the present and proposed programs to meet those needs; establish principles which determine the administrative positions of the respective units in the State health department; seek the establishment of an administrative position for the dental units which will be mutually satisfactory to all concerned and which ultimately will result in better dental public health services for the people; define more clearly the points of agreement and disagreement in regard to the administrative status of the dental unit in that particular State health department.

Recognizing that "blind blames on the medical profession are unavailing" in improving the situation, and that "statements and legislation demanding recognition and status, even if granted, are empty," Dr. Phair expressed the belief also that agreements in meetings composed almost wholly of public health dentists are abortive without demonstration of the fact that dental public health can do a job and without a more concentrated effort on the part of public health dentists in helping their colleagues understand what they are trying to do.

Use of Surveys as Yardsticks In Public Health

The community survey, the professional survey, and the staff self-evaluation study as methods of measurement in public health were discussed in a special session of the APHA. Whether the goal is education of a community about its health responsibilities or measurement of the increase or reduction of a specific health problem, the speakers indicated the surveys were satisfactory techniques, but could be improved by the development of better measuring devices.

Defines Survey Factors To Aid Measurement

In order to establish a common basis for the consideration of public health surveys and evaluations, John D. Porterfield, M.D., M.P.H., director of health, Ohio Department of Health, defined some of the factors involved in public health measurements.

Three Factors

"Need," he said, "refers to the lack of something without which good health is difficult or impossible." He explained, however, that need may not be obvious to the public. For the community population there is instead the factor "want." "And woe betide the health expert who insists flatly on the need for preschool immunization programs when the community wants its children vision-tested," he observed.

"The activity engendered either from needs or wants or from a judicious blending of the two is expressed in 'services,'" he continued. He pointed out that there is a vast difference between the amount of serv-

ices performed and the amount received. Counting the number of doorbells pushed is not quite the same as counting the number of family members who have enjoyed a public health nurse's visit, he explained.

A third factor he noted was community "usage," defined as "the community utilization of a service." Usage alone, he said, is not an accurate measurement of need, for if a community does not "want" the services provided, it will not use them.

Types of Surveys

Mentioning briefly the various ways of measuring these different factors, discussed more fully in succeeding papers, he pointed out that the self-survey by the community very often estimates community "needs" from the viewpoint of "wants." This type of survey, though not highly scientific nor a very exact measurement, is, if properly done, a prime educational tool, he stated.

The professional community survey, on the other hand, usually measures "needs," with only a fleeting reference to "wants," he remarked. He called the professional survey indispensable in developing a pertinent program but suggested that the community may not accept the survey, much less its findings, unless its concern has been aroused.

The professional survey may also be used to compare needs with facilities or services, permitting formulation of judgment as to appropriateness or pertinency of programs, he added. This type of investigation may be requested by the health officer, but more often by the community.

Evaluation or appraisal of public health programs may compare the activity done with the service ren-

dered or the service rendered with the results achieved. "Evaluation is an attempt to determine whether the effects achieved are worth the effort expended or to determine the efficiency of the translation of effort into achievement," Dr. Porterfield said.

Professional Surveys Measure Public Health

Directors of local health departments and other health workers are frequently in doubt about the value and effectiveness of their efforts to improve community health and welfare, stated Ira V. Hiscock, Sc.D., professor of public health and chairman, department of public health, Yale University.

Surveys are helpful in evaluating community health problems and in developing plans to meet them, Dr. Hiscock continued. Administrative surveys include study of organizational structure, review of operating methods, and determination of appropriate areas in which to undertake detailed installation programs. A good survey requires skilled and active staff work, he stated.

"Too much emphasis cannot be given to the need for people with competence to secure and interpret more and better facts in order to show more clearly and precisely what communities can do to prevent and control the problems of the individuals and families," Dr. Hiscock maintained.

When the survey is completed, the professional consultant, "without vested interest or bias," can be of special assistance in interpreting the data collected, he concluded.

Self-Surveys Promote Community Health

The community self-survey of health provides a common ground where professional and nonprofes-

sional persons can meet and work out their problems together, stated Paul A. Miller, B.S., extension specialist in rural sociology and anthropology of the Cooperative Extension Service, Michigan State College.

Sound application of public health practice must involve all members of society, and community health surveys help to shift emphasis from the individual to the family and the community. More and more, participation of local residents in public programs, from planning to tabulation of results, is being encouraged, Mr. Miller said. By taking a look at the health environment in which we live, the recipients of public health services are learning to see their problems from the vantage point of their neighbors, public health workers, physicians, political officials, and others in the public health field.

Community self-surveys of health provide opportunity for instruction and practice in rational, logical, and analytical approaches to the solution of problems. Such surveys reeducate the population of the community and provide an atmosphere conducive to acceptance of the facts about health rather than what is believed to be the facts.

Says Measurement Used Depends on Purpose

Summarizing the preceding discussions on measuring public health, Jack C. Haldeman, M.D., assistant chief of the Bureau of State Services, Public Health Service, said:

"A strong case has been made for each of the methods presented: the community-citizen survey, the professional survey by visiting experts, and continuous self-evaluation by the director and staff of operating health agencies as an integral part of program operation. The time and place for each depends upon purpose. If

a community needs to be aroused to action concerning its health responsibilities, the citizen survey, if properly done, appears to be the most effective education tool. If the goal is scientific measurement of the increase or reduction of a particular health problem, or unbiased appraisal of the administrative efficiency of a health department's organization and management, the professional survey by experts would be the chosen technique. At the risk of overgeneralizing or oversimplifying, one might say that the primary advantage of the citizen survey is to get something started—of the professional survey, to refine what is already in operation."

Dr. Haldeman added that for each type of procedure outlined he would like to underscore the importance of obtaining better criteria as devices for measurement.

"Today's leading public health problems, particularly those associated with the chronic diseases, rehabilitation services, an aging population, and a chemical environment, require a wide range of professional competence and a number of complex facilities and services," he said.

"During recent years," he commented, "we have all become increasingly aware that the newer programs do not always fit into the traditional concept for delivery of public health services. Many local health organizations, as they are now constituted, cannot cope with these problems. This does not mean that local health departments should be strengthened and that new administrative techniques must be developed."

"The answer," he stated, "can only be obtained by determining the real public health needs of the present (as determined by what individuals of the community want and as measured by the experts) and through the evaluation of existing practices to find out how effective they are. Then we can move on to find how they can be improved. The validity of such reassessment of our present

practices is dependent upon the measuring devices we use."

Maryland Study Evaluates Program Efficiency

A study for evaluating the effect of conformance to standards of hospital care for premature infants under way in Maryland was described by Rowland V. Rider, Sc.D., moderator of a panel discussion on measurement of program efficiency.

After outlining the general steps in this type of study, Dr. Rider, assistant professor of public health administration, Johns Hopkins University School of Hygiene and Public Health, described the specifics of the Maryland project:

The standards of care being evaluated, about 90 items, were derived from the recommendations of the American Academy of Pediatrics. Information on the items was obtained at the beginning of 1952 for each hospital by two members of the Maryland Health Department, and a check of the hospitals will be made at the end of 1952.

Each of the items of care was assigned a score, and over-all ratings were obtained by adding the scores on each item. The hospitals were then divided into three groups according to these ratings. The neonatal survival rate in each of the three groups will be the measure of effectiveness of conformance to the standards.

In addition, personal data will be collected on each birth and used to compute rates specific for certain characteristics, such as race, in order to control the influence that differences in these factors among the groups of hospitals would otherwise have on the comparability of the survival rates.

Factors Influencing Outcome

In the discussion following this presentation, one of the panel participants, Edward R. Schlesinger, M.D., director, bureau of maternal

and child health, New York State Department of Health, discussed the difficulty in setting up adequate controls in evaluative studies of public health programs and in weighing various factors making for selection of cases in such studies.

In addition to the factors pointed out by Dr. Rider which may affect the neonatal survival rate, the inclusion in such a study of premature infants brought into the nursery from outside the hospital raises complications, he said. Such infants have survived the first few hours and would therefore seem to have a better prognosis for survival than premature infants in general. On the other hand, very small premature infants and infants doing poorly for any reason are usually selected for transfer to the special premature infant nursery. How to balance one factor against the other in any given situation is almost an impossibility, he remarked.

Other Evaluation Methods

Dr. Schlesinger emphasized, however, the importance and possibility of program efficiency evaluation even when it is not possible to do well-controlled and carefully developed evaluative studies. Evaluation, he said, has all grades of exactness, and as long as the limitations of any method are understood, each type is helpful in the development and improvement of public health programs.

The simplest type of evaluation is the comparison of services being rendered against some yardstick established by accepted authority, he noted. In this type of evaluation, there is no quantitative element involved except possibly the extent of the services in relation to the size of the population serviced.

Another type of evaluation mentioned by Dr. Schlesinger was the measurement of accomplishment against previously established objectives. More quantitative, however, is the measurement defined in mortality or morbidity but without any control, he added.

Every society, every community has its quota of those who are handicapped. And modern societies and progressive communities are ever seeking better ways of helping the handicapped to overcome their problems, particularly children, whose problems are still in the formative stage and are therefore more easily resolved.

No matter what the impairment may be—epilepsy, hearing or speech difficulties, or various orthopedic and neurological handicaps—the crippled child can be and is being helped by both public and private agencies. How this help is being effected and appraisals of its success were reported to the APHA, to the National Society for the Prevention of Blindness, and the American School Health Association.

Mistletoe of Yesteryear Gives Way to Mysoline

Since the days when epileptics drank blood of gladiators in the Roman arena and the doctors prescribed mistletoe collected from the oak at new moon, we have come a long, long way in the treatment of epilepsy. This, Ruth Baldwin, M.D., and associates reported in discussing the epilepsy program in public health. The use of the encephalograph in detecting cases, surgery in correcting, and the use of new preparations, such as mysoline, in controlling seizures, give further promise.

Ten characteristics of epilepsy were listed and examined by Dr. Baldwin, pediatric department, Uni-

versity of Maryland Medical School, and her associates, Edward Davens, M.D., chief, bureau of preventive medicine, Maryland State Department of Health, and Virginia Goddard Harris, M.D., pediatric consultant, bureau of maternal and child health of the department of health. These characteristics suggest that the control of epilepsy is a public health problem of high order:

A chronic disease—A lifetime affliction, epilepsy shares with other chronic ailments the problems and costs of securing competent and continuous service.

The wide prevalence—Approximately 1 out of every 200 persons has the disease in some form.

A disease of childhood—Early case finding and provision for adequate treatment are preventive measures of inestimable value.

Few specialized personnel—And these few are located in large medical centers.

The danger of false labeling—Exact diagnosis is difficult without opinions of several specialists and the use of many tests.

The fog of secrecy—This can be dispelled only through public enlightenment.

The need for education of the public—The health department best can spearhead the attack on fantastic misconceptions and shame which surround the disease.

The difficulty in job placement—More than 75 percent of all epileptics are fully employable. In Illinois, 52 percent of 1,450 epileptics have been placed in full-time employment and disposition is pending in 22 percent, leaving only 26 percent in which the outcome is reported as definitely unfavorable.

The staggering cost to society—Assuming that 1 in 10 of the 200,000 epileptics under 21 years of age in

the United States could become self-supporting, the cumulative economic contribution by these restored persons during their working years, whether in earnings or services, would approximate one billion dollars, and a like amount could be duplicated in each generation.

The urgent need for research and training—The singular contrast between the huge annual cost to society and the negligible amounts spent on research and training points up the urgent need for more centers such as the seizure unit of the Children's Medical Center of Boston where a total care program for hundreds of patients annually is carried out along with research and training.

The Maryland Program

What Maryland is doing to combat epilepsy, through its division of crippled children in cooperation with the medical schools, was outlined by the physicians. Regionalization of the State is materialized by dividing the counties to be served between the University of Maryland clinic and the clinic of Johns Hopkins University. A series of regularly scheduled consultation clinics staffed by physicians from the two centers is conducted in 17 of the 23 counties of Maryland. The major aspects of the program are:

Diagnosis and treatment to all from birth to 21 years of age. Observing priority of emphasis, the program has been directed to the large group of children with convulsive seizures—approximately 80 percent—who are readily amenable to treatment and who do not require institutional or custodial care. Approximately 526 children were examined in addition to a number of adults. These children made 1,102 clinic visits during the year. Of the total number, 212 or 40 percent, were brought in to the central diagnostic-regulatory centers for initial definitive work-up and regulation.

Promotion of public understanding that will bring action through coordination with all other public health services—school health, voca-

tional rehabilitation, citizens' groups such as mental hygiene societies, and crippled children's programs.

Among many case histories cited in the report was one illustrating the part played by psychiatric consultation in arriving at accurate diagnosis and in curing simulated epilepsy. Interviews with the child's parents, who were divorced and remarried, indicated the child was simulating seizures she had witnessed in others. Excellent adjustment followed treatment and placement in a foster home.

Delaware Agencies Unite To Aid Speech, Hearing

An interlocking program to correct the speech and hearing defects of preschool- and school-age children unites Delaware's State Board of Health with the Delaware Hospital and two school systems in a common service, Jack Sabloff, M.D., and L. Leroy Horne, M.A., told the joint session of the maternal and child health section and the American School Health Association.

Dr. Sabloff and Mr. Horne are directors, respectively, of the division of maternal and child health and crippled children's services in the Delaware State Board of Health, and of the Delaware Hospital audiology and speech center, Wilmington.

Workable procedures and a clear-cut understanding of each agency's and individual's part in the program are essential to its smooth running, they said. They described the program as follows:

Schools

Delaware has two public education systems, one in the State and the other in the city of Wilmington. The city, in 1943, initiated a speech correction and reading program which, with a staff of four speech correctionists, a speech reading teacher, and a teacher of the deaf, serves 12,000 children. All other schools except parochial schools are served by the State's

speech and hearing program. Its supervisor of special education and six speech correctionists are responsible for the speech problems of school-age children.

The two systems act for the health department as case-finding agencies, relying on the teacher-nurse relationship. Any child suspected of impaired hearing because of speech deviation, inattention, or history of ear infection is brought to the attention of the speech correctionist for a pure-tone audiometric test. If correction is indicated, he is referred to the State board of health for complete audiologic and otologic evaluation. The family physician is notified of the referral by the school nurse.

Board of Health

The State board of health employed a speech therapist for cerebral palsied children in 1946. Children with cleft palates and others with functional speech disorders were later included in the nucleus of a speech program stressing services for preschool youngsters. As speech problems related to hearing impairments were encountered, the program was expanded to include hearing. A coordinator of speech and hearing, three additional therapists, and an audiologist compose the staff. Diagnostic services and speech therapy are available. Almost all cerebral palsy cases and most cleft palate cases are referred by the schools to the health board. The staff conducts therapy at scattered county health units.

Children are referred to the Delaware Hospital audiology and speech center for otologic and audiologic evaluation and for such recommended treatment at the hospital as tonsillectomy, adenoidectomy, and radium and X-ray therapy. When auditory training, language, and speech rehabilitation are indicated, the board of health utilizes the audiology and speech center for Wilmington children. Children in other parts of the State are trained by its own staff audiologists.

Audiology Center

In 1949, Delaware Hospital started a department of audiology and speech and an audiology center, equipped by the State board of health. The hospital arranged for the center's construction and agreed to support the center and its staff, which is directed by a member of the hospital's department of otolaryngology. The health board set fees and in-patient hospital rates with the hospital. The center's hearing services were expanded in July 1951 to include all speech deviations.

Equipment includes a modern speech-hearing evaluator and an electronic device for psychogalvanic skin resistance testing. Diagnostic audiometric tests and speech-hearing threshold and discrimination testing are performed. Speech and reading therapy, auditory training, counseling, and mental hygiene round out the complete rehabilitation services available. Hearing aids are scientifically selected and evaluated. Complete otolaryngological examinations and treatment and surgical services are provided for health board referrals by the hospital-assigned otologist. The center is staffed by two persons professionally trained in audiology and speech pathology.

Training an Essential In Hearing Programs

Two pitfalls that a public health program for speech and hearing must avoid were noted by Leo G. Doerfler, Ph.D., associate professor of audiology, University of Pittsburgh School of Medicine.

Dr. Doerfler said too much emphasis may be placed upon diagnostic work and sufficient provisions may not be made for adequate follow-up and training. It is not enough, he declared, to demonstrate that the small amount of hearing still remaining in a hearing-handicapped child of

preschool age, for example, can be utilized to pay later dividends psychologically, educationally, and vocationally. If the program does not provide facilities and trained teachers to take advantage of this fact, little has been gained.

Diagnosis involves differential diagnosis of children who do not respond adequately to sound, he continued, not to just a hearing test. He suggested the use of many simple toys and tools in addition to the audiometer and, where feasible, newer instruments such as the psychogalvanometer. All special tests require special interpretation, he pointed out. Moreover, there are vital diagnostic facts, such as parent-child relationships, which are not revealed by any machine, he added.

He also urged, as a correlate to this problem of diagnosis, that recommendations for training and education be realistic. Until facilities are improved and enlarged and new ones opened, raising hope that cannot be practically realized does more harm than good, he maintained.

Hearing Tests

At the preschool level, Dr. Doerfler stated, there are reasonably accurate small-group tests which may determine whether or not the child has sufficient hearing to hear and understand normal speech. Recorded speech is usually the test material, and the responses required are actions rather than speech.

The trend in screening tests for school-age children is toward use of pure tones, administered either individually or to small groups, and away from the use of the phonograph audiometer using words or numbers. Pure-tone tests give more information, are more efficient in case finding, and are about equal in terms of time for administration.

Hearing measurement tests listed included the following: audiometric tests, usually for children above 5 years of age; tests, electronically administered, to determine whether

speech is understood; and special tests, including the so-called conditioning tests. The latter group have much to offer, he remarked, especially for testing children under 3 years old, but much is yet to be learned about validation of the various clinical types before the tests can be employed universally.

Ohio Extends Program To Conserve Hearing

A goal of the Ohio Health Department is to test annually 33 percent of the school population for hearing defects," Margot D. Hartmann, M.D., M.P.H., chief of the division of child hygiene, Ohio Department of Health, reported to the joint session with the American School Health Association.

Five years ago audiometric testing was practically unknown in the smaller school systems of Ohio, the speaker said. Although there was only a 7-percent increase in the total number of school children tested from 1947 to 1951, she stressed that pure-tone audiometric tests were given to 87 percent of all tested in 1951 as compared to 38 percent in 1947. The number of counties giving some kind of hearing test increased from 46 to 81 (out of a total of 88), and the number of cities which include a hearing test in school health programs increased from 31 to 65, she stated.

Local Resources

Local resources are the core of the State's demonstration program, the speaker continued. They are used in planning and audiometric testing, and local specialists are used in rural communities wherever possible.

The coordinating agency for local program planning is the division of child hygiene in the State health department, Dr. Hartmann reported. Highly qualified consultants advise local health departments and schools, maintain liaison with other State agencies, universities, and profes-

sional groups, and assist with testing and interpretation at clinics. Locally, the program is centered in the health department, and emphasis is on prevention and education, she reported.

Training of local personnel is supervised by State consultants, or may be a shared responsibility of State consultants and local speech therapists. Testing methods used must conform to established standards.

Value of Clinic

Although the testing program will show whether or not a clinic is needed, the health department usually requests a clinic to demonstrate the value of adequate diagnostic services, Dr. Hartmann said.

Programs are started only on community request, the speaker said; quality of service, not quantity, has been emphasized; hearing conservation programs were encouraged only when local interest and personnel justified it; follow-up of a few children and correction of all defects found was of first concern. Follow-up care of children examined in clinics or referred to the clinic directly is the responsibility of the community, she stated.

Use of Trailer

A trailer which permits all types of audiometric tests, hearing aid evaluation, and speech reception, has been put into operation, Dr. Hartmann stated. It has been used chiefly in mass education at county fairs, the State fair, and meetings of professional and civic groups. About 3,200 persons of all ages were tested at fairs this summer and referred to physicians if they did not pass the test, she reported. The trailer can be used for vision testing.

Ohio provides scholarships to four to six postgraduate students in audiology, Dr. Hartmann said. Scholastic ability and seriousness of purpose are the only requirements for eligibility, she concluded.

Visual Screen Methods Studied in St. Louis

Discussing the organization of a vision testing research program, Marian M. Crane, M.D., chief of the Children's Bureau child development research branch, reported the following:

The study was carried out jointly with the National Society for the Prevention of Blindness, the Children's Bureau of the Federal Security Agency, the Missouri Department of Public Health and Welfare, the St. Louis Board of Education, the department of ophthalmology, Washington University School of Medicine, and the Office of Naval Research, from February 1948 to June 1949.

Aim of Test

The purpose was to determine the efficiency of some of the procedures frequently used for screening elementary school children for visual defects as measured by the success of the procedures in identifying those students found by ophthalmological examination to need eye care.

Subjects were 609 sixth grade students and 606 first grade students in 14 public schools in St. Louis. Each student received a complete ophthalmological examination which included refraction under homatropine cycloplegia. On the basis of the findings one ophthalmologist recorded a clinical judgment for each child: "refer" if the child needed observation or treatment because of his eyes; "nonrefer" if special eye care was not needed.

The screening procedures studied were teacher observation, the Snellen test, a test of visual acuity at 14 inches using selected lines from the Lebensohn chart for sixth grade and from the Guibor chart for first grade, the Massachusetts vision test, the Keystone View Co. telebinocular, and, for sixth grade students, the American Optical Co. sight-screener and the Bausch and Lomb orthorater.

Methods

Each student was given all of the screening tests (except teacher observation) by each of two testers: a technician who tested all students in the study and the nurse for the school the student attended. In addition, each student was given a Snellen test by his classroom teacher. The amount of preliminary training given these different testers varied and was planned to simulate the amounts that, in a school vision testing program, it would be practical to provide for one tester for many schools, one tester for each school, or each classroom teacher.

The clinical examination and the various tests were administered in randomized order so as to minimize the influence of any learning factor.

A referral by a screening procedure of a student classed as "refer" by the ophthalmologist was considered a "correct referral." Referral of a student placed in the "nonrefer" category by the ophthalmologist was considered an "incorrect referral."

School Nurse Has Job In Vision Testing

The function of the public school nurse in the vision testing research program in St. Louis, Mo., was reported by Annette L. Gronemeyer, R.N., of the St. Louis Board of Education's division of health and hygiene.

Each nurse selected for the eye study was given special instruction regarding procedures and instruments and tests to be used. After being tested with 18 practice cases under supervision, she then was not corrected or assisted unless she asked questions.

Children were tested with glasses if they wore them, and if they wore them only for special purposes they were tested accordingly. Children with defective vision were subject to follow-up routines, in which Miss Gronemeyer reported complete and appreciative cooperation by parents.

The Classroom Teacher Conducts Tests

The procedure in the St. Louis vision testing study is one that any classroom teacher, in the absence of a trained nurse, might use as a preliminary screening, Lula Hack, elementary teacher in the Bryan Mulanphy School, reported. In the study teachers aided in convincing parents of the tests' importance and no children were tested whose parents failed to give consent, Miss Hack said.

Preliminary instructions for participating teachers were given by Dr. Marian M. Crane of the Children's Bureau. Later the teachers received directions for administering the test. Just prior to the actual testing, they were trained by a nurse consultant in the use of the eye chart and the technique of recording observations.

Snellen Test Used

In giving the Snellen test the teachers followed directions of the Massachusetts Vision Test for Elementary Schools. A special biographical form was filled out for each child. For children unable to read, Miss Hack suggested that teachers devise a simple child's game based upon the testing procedure to put the children at ease and to show them how the "fingers" point on the "E" chart.

In giving the tests, the teachers worked independently without coaching and without supervision. All corrections of errors and entries of omissions were made by the teacher, any part of the test being repeated if necessary. Individual tests required 2 to 3 minutes.

A successful teacher must be constantly alert to detect any sign of difficulty that might hamper the child in learning be it impaired vision or impaired hearing, Miss Hack concluded. Having found it, immediate correction or elimination is imperative to the child's well-being.

Laboratory and Field Advances In Food Sanitation

Newer developments in food sanitation and laboratory measurements were discussed by the food and nutrition and laboratory sections, and the problems examined from a variety of angles. It was reported that crushed ice is likely to be of low sanitary quality, that enteric pathogens and coagulase-positive micrococci can be identified in 2 days, that efficiency levels of selenite enrichment broth must be watched. A 4-step test for bacterial contamination of dishes was outlined to a subcommittee; and the engineering section told of the use of isotopes in dishwashing experiments.

Antiseptic Powdered Soaps May Benefit Workers

Industrial use of powdered antiseptic skin cleansers may bring about increased bacteriostatic protection as well as a greatly reduced transmission of communicable disease by skin contact, according to experiments conducted by M. Martin Maglio, Ph.D., chemical director, and John M. Hannegan, Ph.D., manager, respectively, of the industrial skin cleanser division, of Vestal Laboratories, Inc., St. Louis, Mo.

Since the development of effective germicidal bar and liquid soaps, the desirability of incorporating a germicide into industrial cleansers has long been recognized, they said. The industrial worker would thus be less subject to dermatitis, boils, and carbuncles, they said.

In their experiments two antiseptic powdered skin cleansers were prepared, one with a percent hexa-

chlorophenyl, the other with bis-(2-hydroxy-3, 5-dichlorophenyl) methane. A powdered cleanser duplicating the antiseptic ones except for the germicide was used as a control. An ordinary home bar soap was used for comparison. A liquid antiseptic soap containing 2-hexachlorophenyl, standard in many hospitals, was used for comparative purposes.

Washing was carefully controlled. The Cade multiple-basin was the basis for the method used. Rinsings in each basin were sampled, plated, incubated, and the number of colonies present were determined by a Quebec colony counter. The low bacterial counts obtained were clearly not due to bacteriostasis, they stated. The antiseptic liquid soap and the two germicidal powdered cleansers were found equivalent in their effect. The powdered cleansers were 60 percent more efficient than the unmedicated duplicate.

Selenite Broth Media Vary in Efficiency

Greater emphasis on the need to determine the efficiency of selenite enrichment broth is necessary whenever new batches of the medium are to be used or when a change is made in the character of the inoculum, according to W. R. North, B.S., and M. Thomas Bartram, Ph.D., of the Division of Microbiology, Food and Drug Administration.

Deficiencies in the productivity of selenite broth for recovery of *Salmonella* from pure culture and from egg products have been noted, both in commercial products and in media prepared in the laboratory from different types or batches of peptone, they said.

In the isolation of *Salmonella* from egg products, these deficiencies may be overcome in part by the addition of the substance under examination, they stated, and adding cystine in a 10-microgram-per-milliliter concentration further lessens the deficiency in productivity of the broth. In examining substances which do not contribute to the nutritional character of the medium, similar additions of cystine are essential.

Adsorption of Bacteria Hampers Dishwashing

Normal dishwashing methods will dislodge only a small fraction of some types of organisms strongly adsorbed on eating utensil surfaces, reported Gerald M. Ridenour, Ph.D., associate professor of engineering, and Edward H. Armbruster, research associate, University of Michigan School of Public Health.

The researchers investigated the bacterial cleansibility of glass, china, steel, plastic, and aluminum, using P³² tagged bacteria, and measuring by the radioactive count method. Their studies covered the relative retention of different bacteria on different type eating utensil surfaces, different conditions of surfaces, absence and presence of organic soil, and soil film build-up resulting from repeated soiling and washing.

Adsorption Characteristics

Other results of the experiments follow:

The strength of adsorption varies with type of organism: some are lightly adsorbed, others strongly. Adsorption of the organism is specific for a surface.

Of the organisms studied, *Micrococcus aureus* was the most difficult and *Escherichia coli* the easiest to remove from a given surface.

In the absence of soil, percentage removal of *M. aureus* from china, glass, and steel surfaces, with standard detergency and temper-

ature conditions, was between 97 and 99+, but between 56 and 84 on plastic and aluminum surfaces. The large variation noted on plastic eating surfaces did not exist among china or glass surfaces.

With *E. coli* in the absence of soil, ease of removal increased for all surfaces, varying between 99 and 99+ percent for china, glass, and steel, and between 90 and 98 percent for plastic and aluminum.

When the bacteria were mixed with an organic soil, the efficiency of removal increased markedly for all surfaces. When the bacteria were overlaid with the organic soil, efficiency of removal from plastic surfaces dropped quite markedly in relation to china, glass, and steel.

When plates were worn or scratched, removal efficiency decreased for all surfaces, but the same relation existed between different surfaces as with the unworn surfaces.

4-Step Method Measures Dish Contamination

Additional experimental work in determining the bacterial contamination of dishes was described by Albert F. Guiteras, Ph.D., director, Hudson Laboratories, Inc., New York; Lawrence H. Flett, B.S., director, new products division, national aniline division, Allied Chemical and Dye Corp., New York; and Rebecca L. Shapiro, chief bacteriologist, Hudson Laboratories, Inc.

This method, the authors reported, is designed primarily for research work and for routine regulatory health control purposes. It involves four steps; (1) placing the dish to be examined as a cover over a Petri dish containing melted tryptone glucose extract agar at about 45° C.; (2) inverting the two dishes so that the Petri dish is on the bottom; (3) allowing the agar to harden at room temperature; and (4) incubating the set-up for 48 hours at 37° C. After incubation the dish is removed, leaving the agar in the Petri dish

where the colonies are counted with the aid of a Quebec colony counter.

The authors reported two experiments using artificially contaminated plates. A comparison of this method with the swab contact method revealed that the total number of organisms recovered by the new method was quantitative, within the limits of experimental error, whereas the number recovered by the swab contact method was significantly lower, even with the use of two swabs.

Series of Tests Reveals Crushed Ice Is Unsanitary

Ice as dispensed at many eating establishments is of extremely low sanitary quality, V. D. Foltz, M.S., Kansas Agricultural Experiment Station, Manhattan, Kans., stated in a report on a study of 114 samples collected from hotels, restaurants, soda fountains, and hospitals in central Kansas.

Presenting detailed results obtained from physical and bacteriological examination of crushed ice and of cubed ice from automatic ice machines, Mr. Foltz reported that:

Only 27 samples were of acceptable quality, using absence of coliform as the criterion of potability.

Of the 77 samples of commercial crushed ice, only 10 were free of coliform organisms, indicating gross contamination during grinding, sizing, bagging, and delivery to the consumer, since samples of cake ice from which crushed ice is made were found to be entirely satisfactory.

Of 37 ice-cube samples, 17 were coliform negative. Ten of these samples were collected from hospitals, and all were negative for coliform and clostridia, demonstrating that ice-cube machines can be operated in a sanitary manner and the product dispensed in good condition.

Of 32 ice-cube samples examined for micrococci and streptococci, 22 contained the former and 19 the lat-

ter; these organisms were found in only one of the 10 hospital samples.

Inert material found in the samples included sand, clay, assorted colored fibers, assorted colored thread, vegetable fiber, fingernail-polish scales, insect fragments, rodent hairs, human hairs, and wood splinters. Although this material is not a direct criterion of bacterial pollution, it indicates the extent to which the product may have been polluted, Mr. Foltz remarked. The ice-cube samples were remarkably free of dirt, the hospital samples containing the least amount.

Rapid Coagulase Method Equals Routine Test

A survey among 341 food handlers to determine the carrier rate of coagulase-positive micrococci revealed that 73 (38 percent) of the 191 males and 56 (37 percent) of the 150 females examined were nasal carriers of this causal agent of staphylococcal food poisoning, reported S. J. Millian, M.S., H. H. Weiser, Ph.D., J. M. Baldwin, Ph.D., and J. M. Birkeland, Ph.D., of Ohio State University's department of bacteriology.

These carrier rates, determined at the university's dining halls, are 5 to 10 percent less than those reported by investigators of other groups, they said, and were found to be unaffected by the age or sex of the food handlers.

A study of the distribution of penicillin-resistant coagulase-positive micrococci was also made. Twenty-seven percent of the male and 23 percent of the female carriers were found to harbor penicillin-resistant strains.

A new method was developed which can detect carriers of coagulase-positive micrococci within 24 hours. After sampling, the nasal swab is put into a 12 ml. centrifuge tube containing 5 ml. of BHISB (brain heart infusion salt broth) and is incubated at 37° C. for 20

hours. The broth is then centrifuged, the supernatant decanted, and 0.5 ml. of fresh citrated whole rabbit blood is added to the packed cells. The suspension is thoroughly shaken and transferred to agglutination tubes which are incubated in a 37° C. water bath for 3 hours. The contents of the tubes are then observed for coagulase activity.

The efficiency of this accelerated method, they said, was comparable to the routine procedure using sheep blood agar and lactose salt agar.

The study also revealed, they concluded, a high correlation existing between chromogenesis on lactose salt agar and coagulase production.

Salmonella and Shigella Identified in 2 Days

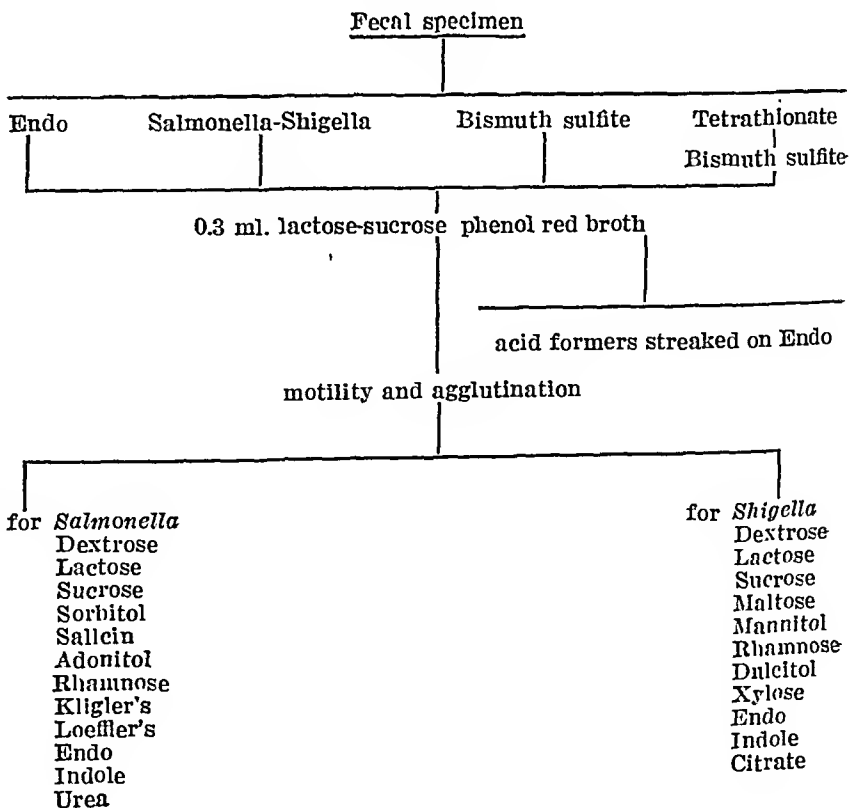

Enteric pathogens can be isolated and identified from stools in 2 days

by the method recommended by Robert A. MacCready, M.D., and Marion B. Holmes, B.S., assistant director and junior bacteriologist, respectively, of the Institute of Laboratories, Massachusetts Department of Public Health.

According to their report, the method involves the fishing of colonies from the primary plates into small lactose-sucrose broth tubes (0.3 ml. of broth), incubation for 1-3 hours in a 37° water bath, performance of hanging drop motility and agglutination tests, and inoculation of the confirmatory carbohydrates, all on the same day. This procedure, they said, saves a day over the customary double or triple sugar agar screening techniques. (See chart.)

They also described a method, employing the so-called micro-techniques in all the confirmatory tests, whereby *Salmonella* can frequently be identified only 7 hours after the fishing of the colony and *Shigella*, the following morning.

Outline of procedure for identification of *Salmonella* and *Shigella*

Importance of Animal Diseases To the Health of Man

Problems of animal diseases as they relate to the health and welfare of man were presented at several section meetings. Studies of sporadic bovine encephalomyelitis and an outbreak of psittacosis were reported to the epidemiology section; the effect of mass immunization of dogs against rabies, to the laboratory section. A joint session of the epidemiology and laboratory sections discussed leptospirosis. A paper on foot-and-mouth disease as a threat to the United States and papers on poultry as a potential source of viruses pathogenic to man and on progress in grading poultry and in poultry dressing sanitation were given at a joint session of the engineering, epidemiology, food and nutrition, and laboratory sections.

Foot-and-Mouth Disease Threats Emphasized

Foot-and-mouth disease is the primary animal disease menace in the world, declared M. S. Shahan, D.V.M., of the U. S. Department of Agriculture's Bureau of Animal Industry.

The United States has experienced the disease nine times, the last outbreak occurring in 1929, said Dr. Shahan. The earlier infections were mostly introduced by live animals from infected countries but several times the disease gained entry through infected animal products.

He felt that the United States is fortunate in its comparative geographic isolation and in its largely self-sufficient livestock production, but it still is necessary to import large quantities of animal products.

The difficulties in this country, he said, are complicated by the occurrence of two virus-induced vesicular diseases—stomatitis and exanthema—which are clinically indistinguishable from foot-and-mouth disease. He warned that although it has been 23 years since an occurrence of the disease, there is constant danger of its introduction.

Dr. Shahan described various possible means of eradication through widespread inspection, quarantine, destruction of infected and exposed animals, and disinfection of premises. He emphasized that importation into this country of cattle, sheep, swine, goats, and other susceptible animals—and any meats of these species—is prohibited from any country classed as infected. The Bureau of Animal Industry with the aid of other Federal agencies supervises and inspects such international commerce, he said, and often even garbage from planes and ships is refused entry for livestock feed since it may contain infected meat scraps that could introduce foot-and-mouth disease.

Possible Impact

Although the task of protection is tremendous, he continued, the impact of the disease here could be disastrous since it involves the entire national economy. The productivity of the susceptible species might well be reduced by 25 percent or more, he said, and such a great loss would be multiplied by the stringent quarantines necessary for control.

Dr. Shahan felt that H. S. Frenkel's laboratory success in cultivating an adequate virus vaccine—utilizing minced tongue epithelium in a nutrient synthetic fluid medium—is a significant step toward solving one of the major problems of vaccine production in this field.

In continuance of this country's

vigilance against a possible future outbreak of the disease, he reported that facilities for safe, scientific investigations will be completed by 1954 on Plum Island, in Long Island Sound, N. Y. Congress has already appropriated funds for this project, he said, and plans for its development are now being made.

Bovine Encephalomyelitis In Western Cattle

The agent of sporadic encephalomyelitis has been linked to the psittacosis-lymphogranuloma group of viruses, according to Herbert A. Wenner, M.D., of the University of Kansas Medical Center, Kansas City, Robert W. Menges, D.V.M., epidemiology branch of the Public Health Service Communicable Disease Center, Kansas City, Gerald S. Harshfield, D.V.M., veterinary department of the South Dakota State Agricultural Experiment Station, Brookings, and Te Wen Chang, M.D., fellow of the Haynes Memorial Hospital, Boston.

Dr. Wenner and his associates found encephalomyelitis widespread among young cattle in the midwestern States, with immunity relative or absolute in many adult cattle. An association of human illness with herd outbreaks has not been observed, but these studies are incomplete. Serologic evidence suggests that human beings may have illnesses, yet unrecognized, caused by BEV (bovine encephalomyelitis virus), they stated.

Symptoms Observed

Dr. Wenner pointed out the epidemiological and epizootiological implications of the disease and described the symptoms observed in sick cattle. Morbidity rates for calves averaged 30 percent; mortality rates varied from 20 to 100 percent. Sharply localized epizootics have broken out among herds into which calves purchased from dealers were introduced. The velocity of infection was usually swift and the duration of the illness averaged 4 weeks, the study revealed.

Necropsies showed a seropurulent exudate involving pleural, pericardial, and peritoneal surfaces. Microscopic examination showed fibrinous serositis and meningoencephalomyelitis.

When tissues from affected calves were inoculated into guinea pigs and into developing chick embryos, illness or death of the experimental host resulted. Minute elementary bodies indistinguishable from those of the psittacosis-lymphogranuloma venereum group were found in both hosts. Antigens prepared from the strains of the virus (BEV) fix complement with specific serums.

Cattle with naturally occurring forms of the disease, as well as those experimentally infected, developed CF antibodies (BEV), the researchers reported.

Rabies Problem Attacked Successfully in St. Louis

Since 1921, rabies has become an increasingly important and complex public health problem in St. Louis, Mo., reported Rabies Control Officer Luther E. Fredrickson, D.V.M., Deputy Health Commissioner Joseph C. Willett, D.V.M., and Health Commissioner J. Earl Smith, M.D., all from the St. Louis Department of Public Welfare, and E. R. Price, D.V.M., public health veterinarian, Missouri Department of Public Health and Welfare.

Six rabies epizootics have occurred in St. Louis since 1921 and each outbreak has been more serious and longer than previous ones. Therefore, according to the health officials, after conferences with local veterinarians and State health officials the St. Louis health commissioner—on advice of an investigating Public Health Service veterinarian—recommended in 1951: (1) mass immunization clinics; (2) an educational program for dog owners; (3) health division control of stray dogs; and (4) an immediate ordinance requiring annual vaccination for all dogs and permanent control of the dog pound by the health commissioner.

A quarantine order requiring every dog in St. Louis to be immunized against rabies and confined to the owner's premises was immediately issued and an emergency fund of \$25,000 was authorized for a mass antirabies program. By June 1, 1951, some 58,000 dogs—70 percent of the city's dog population—were immunized against rabies in public clinics or by private veterinarians.

The results were significant, the officials continued. In August, 2 months after the closing of the public clinics, only one rabid dog was reported, as contrasted with 79 in May. Eighteen dogs were diagnosed as rabid from July–December of 1951 as compared with 309 for the first 6 months of the year, and the incidence has remained low in 1952. However, because of only sporadic control attempts in the metropolitan areas immediately adjacent to St. Louis, Mo., the incidence of rabies there has continued at a relatively high rate.

They concluded that an intensified program of inoculating a high percentage of the canine population in a short period of time is much preferable to sporadic inoculation of small numbers over an extended period.

Techniques for Confirming Leptospirosis Diagnosis

Laboratory confirmation of leptospirosis may be most readily and reliably made by employment of direct blood-culture methods and serologic examination by complement-fixation employing sonic-vibrated leptospiral antigens, reported Maj. William S. Gochenour, Jr., D.V.M., Lt. Col. Robert H. Yager, D.V.M., Joseph E. Smadel, M.D., Psyche W. Wetmore, B.A., and Capt. John A. Hightower, M.D.

Major Gochenour and Lieutenant Colonel Yager, of the U. S. Army Veterinary Corps, are deputy director and director, respectively, of the veterinary division, Army Medical Service Graduate School, Walter

Reed Army Medical Center. Dr. Smadel is director of the school's communicable disease division; Mrs. Wetmore is with the department of veterinary bacteriology; and Captain Hightower, of the U. S. Army Medical Corps, is with the Tropical Research Medical Laboratory, San Juan, Puerto Rico.

The researchers based their report on studies of 79 bacteriologically proved human cases of acute leptospirosis encountered in Puerto Rico from October 1950 to May 1952. They described in detail the techniques employed in confirmation of the clinical diagnoses and in determination of responses to antibiotic therapy.

Blood cultures should be made during the initial febrile stage of illness, they noted, and serial serum specimens, the first obtained early in the disease, are essential to the demonstration of the diagnostic rise in antibody level.

They announced that both of the procedures recommended are within the capabilities of the routine diagnostic laboratory. Identification of leptospiral strains isolated requires the employment of antibody adsorption techniques and is best accomplished at a leptospiral reference laboratory, they added.

They expressed the opinion that existing knowledge of the antigen-antibody reactions in the leptospirosis does not encourage the hope that new serologic techniques will materially reduce the time required to confirm the diagnosis of leptospirosis. It would appear, they said, that the most promise lies in the direction of earlier detection of leptospirae than is possible with existing methods.

Advances in Leptospiroses Depend on Laboratory Aid

In another paper, Lieutenant Colonel Yager and Major Gochenour suggested four measures for advancing the investigation and control of

the leptospiroses and indicated areas of deficient knowledge in the field.

Most important, they said, adequate support should be made available for basic research into the epidemiology, epizootology, prophylaxis, and control of the leptospiroses. This implies support of fundamental study of the organisms and of the pathogenesis of these diseases, they explained.

A second measure recommended was the establishment of diagnostic laboratory services at the Federal, State, county, and city levels; a third, the establishment of a reference laboratory, comparable to the salmonella typing center at the Public Health Service Communicable Disease Center, to provide definitive identification of leptospiral isolates and technical assistance to the diagnostic laboratories.

Drs. Yager and Goehenour also suggested that leptospiroses in man and domestic animals be placed on the list of reportable diseases. Recognizing the administrative burden inherent in such a step, they nevertheless consider reliable incidence, morbidity, and distribution statistics necessary to the realistic evaluation of the significance of the leptospiroses.

Organism Characteristics

Progress in diagnosis, prophylaxis, and therapy, they said, hinges upon knowledge of the infecting agent itself. Although certain characteristics of the leptospirae have been established, their nutritional requirements, metabolism, and enzyme systems are not known. "Determination of optimal nutritional and environmental requirements for leptospiral cultivation would not only assist in the prosecution of investigative studies," they noted, "but would materially increase the value of culture examination as a diagnostic procedure."

Concerning the epidemiology of the leptospiroses in the United States, the veterinarians pointed out that animal reservoirs of three strains have been established; three lepto-

spiral infections have been recognized only in man; and one has been found only in rats and mice. "It is essential not only that the animal reservoirs of infection be determined, but that the mechanism of transmission of infection to man be demonstrated," they stated.

Therapy and Prophylaxis

Information on therapy is also meager, they said. Reports too often deal with a limited series of patients and are often based upon clinical impressions alone. Excellent studies have been conducted in the laboratory animals on antibiotic therapy, but the encouraging results obtained cannot be translated directly to man or the domestic animals. At present, definitive therapy is limited to the use of aureomycin or streptomycin in dogs.

"Studies on vaccination prophylaxis have been limited to dogs," they continued, "and here a satisfactory vaccine against one strain only . . . has been devised. The problems in development of satisfactory vaccines, though not insurmountable, are formidable. To be of value, such vaccines must protect against all strains known to occur in the species in the United States. Further, not only must clinically apparent disease be prevented, but inapparent renal carrier states as well. This requires a most critical and careful evaluation of vaccines developed in the future."

Suggests New Controls On Psittacine Birds

Further study of psittacosis and some form of renewed control over traffic in psittacine birds were recommended by Theodore S. Drachman, M.D., M.P.H., first deputy health commissioner, Westchester County, N. Y., Department of Health.

After relaxation of foreign quarantine restrictions and removal of interstate barriers, New York revoked controls on the importation,

breeding, and sale of psittacine birds early in 1952. In May 1952, two outbreaks of psittacosis occurred in Peekskill and Ossining, N. Y., both in Westchester County, Dr. Drachman said. The last previously reported cases in the county had occurred 10 years earlier.

Three cases of psittacosis were confirmed in each series, with the possibility of a fourth case in Ossining, and as many as four or more additional cases in Peekskill. The Ossining episode was a typical household outbreak. The one in Peekskill occurred among employees in a chain department store selling parakeets, along with other birds. No connection has been established between the infected birds responsible for the two series of cases, Dr. Drachman said.

Presents Facts

Dr. Drachman reviewed the following facts in the light of the Westchester experience:

There appears to be a generalized endemicity of psittacosis on certain bird farms in Florida and some other States. Despite control measures imposed in Florida aviaries where the disease is known to exist, it is impossible to say with absolute assurance that birds shipped from Florida or anywhere else in the country are free from psittacosis.

When blood sent to laboratories for other types of examination is tested for psittacosis antibodies, a far from routine laboratory procedure, unsuspected cases are discovered. The possibility of many missed cases is suggested. In half of these cases, inquiry failed to reveal birds or mammals in the patients' environment.

The case fatality rate, as high as 40 percent in the past, has been reduced to 2 percent with antibiotics. Yet little appears to be known of the possibility of developing fastness to antibiotics. In the few Westchester cases, although there were no fatalities, relapses and prolonged convalescences were not prevented by antibiotic therapy.

To Be Answered

Dr. Drachman recommended further study of these questions:

Why is psittacosis highly communicable and dangerous to laboratory workers, moderately communicable on contact with infected birds whether apparently ill or not, and difficult to contract from a human case?

What is the actual psittacosis experience of the general population? Is it a common disease, or a rare one as has been believed?

What are the factors that determine human susceptibility?

Are there differences of epidemiological importance in the psittacine and nonpsittacine strains of the virus as implied by the separate terms of psittacosis and ornithosis? Is there a significant difference in the indoor exposure to a pet and to infected poultry outside?

What is the likelihood of a human carrier of virus, casual or otherwise, infecting a previously healthy household pet which may then become a health menace?

Poultry Grading Program Continues to Grow

Interest of public health groups in the U. S. Department of Agriculture program of grading poultry on a voluntary basis is stimulating health departments to give special attention to the drafting of sanitation standards for poultry plants, said Alfred H. Fletcher, M.S., director, division of environmental sanitation, New Jersey State Department of Health.

Mr. Fletcher also reported that as a result of the mutual interest of national health groups, the poultry industry, and the Department of Agriculture in better grading standards, the department's grade label will not be stamped on eviscerated poultry after June 30, 1953, unless the poultry has been inspected for wholesomeness and processed under sanitary conditions.

"It is hoped that this action will tend to further encourage the processing of poultry in the ready-to-cook form," he said, remarking that it would be highly desirable from the public health standpoint.

Other Achievements

Reporting on other achievements of the voluntary program, he said:

Poultry inspection in 1952 has increased about 40 percent over 1951. Approximately 17 percent of the total poultry sold on a dressed weight basis is inspected. About 100 million more pounds of poultry were graded in fiscal year 1952 than in 1951. Grading service is now maintained in 312 processing plants. More than half of the poultry sold from farms in fiscal 1952 moved in ready-to-cook form at the processor level. And almost 800 million pounds of poultry were inspected for wholesomeness.

The voluntary program depends on the cooperation of the processor and the willingness of the consumer to pay the extra cost of the grading service, Mr. Fletcher stated. It is under the Department of Agriculture's Production and Marketing Administration and provides services at each plant, for each bird.

"A sound Federal poultry grading inspection program is considered basic to the development of sound local public health programs," Mr. Fletcher declared. The Federal program sets the pace for content and standards, and the plants under its supervision form the nucleus around which States develop their local programs, he indicated.

Viruses Pathogenic to Man Carried by Poultry

Poultry must be regarded as a potential reservoir of viruses pathogenic to man, warned H. J. Stafseth, D.V.M., Ph.D., head of the department of bacteriology and public health, Michigan State College.

Dr. Stafseth based this premise on a review of the literature of the bacterial and viral diseases which afflict poultry. However, he stated that although some two dozen poultry diseases are communicable to man, at present most of the cases of human illness contracted from poultry have been confined to individuals or small groups, that very rarely have considerable numbers of people been affected.

He listed salmonellosis, psittacosis, erysipelas, and Newcastle disease, as those with most public health significance.

Four Government Agencies Concerned With Poultry

The Food and Drug Administration, the Public Health Service, and the U. S. Departments of Agriculture and Defense are all concerned with poultry dressing sanitation, and each performs activities clearly defined through public law, but all work together to obtain a unified program, stated Harry E. Goresline, Ph.D., chief, stability division, Food and Container Institute, Chicago Quartermaster Depot, U. S. Army, Chicago.

The Food and Drug Administration is concerned with poultry products in interstate commerce or products being processed for that purpose, he noted, the aim being to prevent shipment of birds diseased, improperly processed, filthy, decomposed, or in any way injurious to health. Market surveys regularly determine the quality and condition of the poultry products being sold, and a regular program of sanitary inspection of poultry plants is carried out. Legal action may be taken against processors when objectionable conditions are found.

The Public Health Service provides advisory, information, and consultation services for other Federal agencies, the States and their political subdivisions, and food industries,

Problems, Methods, Programs In Community Fly Control

Dr. Goresline said. He remarked that the Service has initiated field studies on the sanitation problems of the poultry industry and intends to develop sanitation standards, covering inspection for wholesomeness, which can be incorporated into a model standard ordinance. The ordinance, of course, will be for voluntary adoption by States, cities, and other jurisdictions concerned, he added.

Agriculture and Defense

The U. S. Department of Agriculture offers poultry inspection and grading services to individuals, processing plants, or other interested parties upon request. An applicant for such services must comply with certain sanitary regulations and pay the costs of the services. The purpose of poultry inspection, he explained, is to determine, during the eviscerating operation, the condition, healthfulness, and fitness of poultry for human food and the wholesomeness of edible parts or processed products produced from inspected poultry. Poultry grading involves the sorting of individual carcasses as to quality and size and the determination of class and condition.

The poultry sanitation program in the U. S. Department of Defense, he continued, is centered around the procurement of poultry meat for the armed forces. The awarding of contracts for poultry meat is limited to approved plants or to those operating under the Department of Agriculture poultry inspection service. If only dressed poultry is produced, the operation must be carried out under the supervision of armed forces veterinarians, he noted. However, if various types of ready-to-cook or canned poultry products are being produced, the plant must be operated under the supervision of the poultry inspection service of the Department of Agriculture. The actual inspection of the product is a responsibility of the armed forces, he added.

Community fly control operations in various parts of the country were described in papers presented before the Conference of Municipal Public Health Engineers. In Kansas City, Mo., special fly problems were created by the flood of Missouri-Kansas Rivers in 1951. In Phoenix, Ariz., a fly control program is devoting its major efforts to correcting insanitary conditions, particularly the indiscriminate dumping of wastes from the vegetable-packing industry in the State. The Texas program is described as "just plain community sanitation, glamorized with the magic of wonder chemicals and systematized by fly density estimating techniques."

1951 Kansas River Flood Creates Fly Problems

Fly counts during the height of activities in the wake of the Kansas River flood, July 1951, ranged from 2 to 500 per square yard in the central industrial district of Kansas City, Mo., and averaged 150 per square yard in other areas studied, Carl C. Potter, B.S., commissioner, public health engineering, Kansas City Health Department, stated.

Immediate health problems during and following the flood were lack of drinking water, disruption of plumbing and garbage collection, proper housing, food service in establishments allowed to operate, and the expected prevalence of insects when the waters subsided. Garbage collection was disrupted when vehicles were caught in the flood. This factor and an estimated 15,000 dead stockyard animals

caused the health department immediate concern in regard to fly control, Mr. Potter said.

The animal carcasses were dumped into the river, and were immediately carried on into the Missouri River. This practice continued for 6 days until trucks and equipment were available to transport the dead animals to landfill dumps.

As the flood subsided it was clear that the dead animals were not the greatest source of fly-breeding problems. The clean-up had been rapid enough to keep this under control, the speaker continued. Damaged seed, grain, and foodstuffs which had taken more time to remove were found to be the heaviest breeding places for the flies.

Control measures consisted of the use of 8,800 gallons of 0.5 percent BHC emulsion in larviciding, 450 gallons of 5 percent DDT emulsion in residual spraying, and 330 gallons of 5 percent DDT and 2 percent chlordane emulsion in space spraying. The spraying and larviciding were continued until the entire district was cleaned up and business resumed operation.

Control Effort Makes City Less Attractive for Flies

Although temporary fly control measures, such as space spraying, are occasionally utilized, the major efforts of the Phoenix, Ariz., program are devoted to eliminating insanitary conditions, said Jerrold M. Michael, M.S.E., superintendent of sanitation, Phoenix Public Health Department.

The major sanitation problems given attention, according to Mr. Michael's report, were chicken and animal pens; refuse storage, collection, and disposal; substandard

sewage disposal systems; large-scale commercial animal feeding operations; food processing plants; waste vegetable disposal fields; and waste water disposal from evaporative cooling systems. An example of permanent corrective measures instituted, he said, is a newly developed process of waste vegetable reclamation.

"In past years, culls and wastes from the vegetable-growing industry of Arizona have been dumped wherever the packer could find available space," he explained. "As the area around the packing shed became more urbanized, the fly problem . . . grew steadily worse." A solution having economic value as well as eliminating fly breeding spots was the adoption of a method of recovering the vegetable wastes for livestock feed.

Other accomplishments of the 4-year-old program included: installation of 13,000 new garbage containers; wrapping of garbage by 75 percent of the housewives; purchase of 9 new packer-type garbage collection vehicles, increasing the number to 14; establishment of a sanitary landfill, practically eliminating the feeding of garbage to hogs; 75-percent reduction in number of animal pens and 51-percent in number of fowl pens; elimination of 324 privies; and renovation of waste disposal systems in four abattoirs.

Program Development

He named as essential steps in developing a fly control program: establishing interest among city officials, the public, and the staff who will operate the program; defining specific problems needing attention; training a staff; and finally, applying control and inspection measures.

He pointed out that it is particularly important, in defining the problem, to include in the program the area surrounding a city's corporate boundaries, as "the fly . . . is a notorious violator of 'City Limits' signs." Once the extensiveness of each problem is determined, decisions may be made as to the problems to receive initial efforts,

although, of course, many of the problems will be interrelated, he added.

Mr. Michael emphasized that the fly control staff should work closely with other members of the sanitation staff, particularly milk and meat inspectors and the sanitarians who inspect restaurants, groceries, hotels, and bottling plants. These sanitarians can incorporate fly control measures into their routine inspections, he explained. A close liaison should also be maintained with the city's refuse collection authorities.

More Communities Adopt Fly Control Programs

Education—sanitation—spraying!

These are the three steps vital to every successful community program for fly control, and more such local programs must be developed if the annual 9,000 deaths from fly-borne dysentery and diarrhea in the United States are to be reduced, said Joseph H. Coffey, B.C.E., and Paul W. Purdom, M.S.E., of the Public Health Service's Communicable Disease Center, Atlanta, Ga.

To encourage this development, they said, the Public Health Service inaugurated, in 1950, a CDC program to demonstrate to State and local health agencies how fly control could be achieved by communities.

They reported that seven demonstration projects were established in four States with high incidence of fly-borne dysentery—two each in Arizona, New Mexico, and Texas, and one in Kentucky. CDC provided technical personnel and guidance for the projects, but all costs of sanitation measures, spray materials, and their application were assumed by the communities.

Emphasize Prevention

The three-point program emphasizes that "the [best] way of attacking [flies] is to prevent them from breeding," and is applicable to most communities, they continued. In the initial educational phase, they explained, the entire community—indi-

viduals and groups of all types: housewives, pet owners, restaurateurs, farmers, food processors, and others—must be informed of the nature, habits, and preferred breeding places of flies, their danger to the community, and what can be done to eliminate them.

Second, adequate sanitation facilities must be provided in the community to eliminate fly breeding sources, they said. The demonstration program indicated that sanitation measures should be concentrated on refuse and on human, animal, and industrial wastes. They emphasized that not only should privies be eliminated, and frequent and thorough collection and disposal of refuse be made, but that all homes should be connected to existing sewers with new sewers extended to unserved areas.

Although these permanent accomplishments are generally more economical and effective to the community than are temporary measures, they are slow to achieve, they reported. Immediate sanitation needs can be satisfied by judicious chemical spraying of key breeding locations, they said, provided adequate consideration is given to the species of flies present and the chemicals and application methods required to eliminate them.

The fly control program proved effective in the demonstration projects, they reported, and 34 additional cities have adopted its principles, partly or wholly, under completely local sponsorship. Supervised by State fly control specialists, some cities have hired and trained their own control personnel, and many others are requesting technical assistance from State health departments.

Texas' Fly Control Plan Sparks City Development

Texas' fly control program is stimulating modernization of city facilities and plans for future community development, reported Clay-

ton H. Billings, M.S., senior engineer, Texas State Department of Health.

"Just plain community sanitation, glamourized with the magic of wonder chemicals and systematized by fly density estimating techniques, is our fly control program of today," he said.

Texas found that carrying a fly control program to completion meant overlapping in other health fields. Privy elimination meant sewer extensions. Sewer extensions led to enlargement of treatment plants and water system extensions, sometimes requiring increased water supply capacity. People even repainted and remodeled their homes.

One real estate developer began a subdivision of low-cost homes after learning that people living in a substandard environment would cooperate in a garbage storage and privy elimination program, Mr. Billings said.

In Kingsville, all oil drums customarily used for garbage storage were confiscated, and the city purchased 85 dozen standard containers for sale, even on credit terms, to the public at acquisition cost, he reported.

Brenham maintains all privies at cost to the householder. As sewers are completed, Brenham eliminates privies by merely reclaiming its property, he said.

Privies which could not be removed through lack of available sewers were factors contributing to high grill counts. This led to the use by the State of 10 percent DDT dust in privy vaults and, later, 3 percent BHC dust.

No Organization Conflict

Vector disease control is under the bureau of sanitary engineering, which also handles other environmental sanitation, Mr. Billings said. He explained that policy and jurisdictional decisions presented no conflict since all projects were cleared at the State level and through the bureau's field offices.

Two demonstration projects were conducted in central Texas and near the Gulf Coast in 1950. Eight cities in 1951, and 28 in 1952, responded by undertaking locally financed projects. In the program expansion, it was planned to select sites significant from a diarrhea-dysentery standpoint and geographically located to influence surrounding areas, Mr. Billings remarked.

Most projects, however, were requested by city officials, some after an epidemic or disaster. One followed the 1951 polio and dysentery epidemic in Corpus Christi. An original control town, Mathis, "grew tired of being held a bad example and insisted on instituting standard fly control procedures," he said. Olney set up a project after a severe disaster. Strategically located projects were undertaken at Henderson, Braunfels, Midland, and Brownwood.

Fly control schools gave municipal officials a 3-day training in the use of insecticide application equipment,

fly grill counting methods, and other techniques. Thirty-one schools were held in 23 locations, he reported.

Corpus Christi's Control

In Corpus Christi, block-by-block premise inspection was conducted in substandard areas by a health unit sanitarian, a voluntary worker, and a police officer. In 1952 there were only 320 privies left from the original 1950 count of 2,446 privies within city limits. Enforcement of the plumbing ordinance since 1950 has converted to individual units 490 of about 700 community toilets serving two or more houses, he reported.

Mr. Billings compared the 30 infant diarrhea deaths in 1951, and 7 so far for 1952, with the 10-year average of 90.3 per year for Nueces County in which Corpus Christi is located. This improvement, he said, was attributed by the city-county health director to the combined efforts of the fly-control program and the well-child conferences.

Varied Methods and Practices In Providing Medical Services

A variety of methods and practices in the provision of medical services were described before sections of the APHA and associated groups in Cleveland. Rural group practice in a low-income community over a 6½-year period was reported, along with 8 years' experience with a group indemnity program in a metropolitan area. New York's Health Insurance Plan was described, as was the 6-year-old industrial program for hotel workers. From San Francisco came the story of multiphasic screening of longshoremen, and

hospital consultants heard a plea for a functional approach to hospital architecture.

County Group Provides Care in Reach of 90%

An example of providing a low-income community with the best available in medical care at a cost that at least 90 percent of the people can afford was cited by Caldwell Blakeman Esselstyn, M.D., medical director of the Rip Van Winkle Clinic, Hudson, N. Y., in his description of 6½ years' experience of group practice in that rural area.

Established under the aegis of a nonprofit, tax-exempt corporation, the clinic is staffed by 17 doctors. Services in 14 areas of medicine (including psychiatry) and dentistry are provided.

To make clinic membership attractive to physicians, immediate financial security is provided through salaries, cases are distributed in accordance with the various specialties, regular luncheon meetings are held for the staff, and fortnightly meetings are addressed by medical leaders in all fields. Provisions have been made for teaching responsibilities at the nearest medical center and the clinic has made available a current reference library and funds to enable the doctors to attend important conferences.

Branch Centers

To serve the outlying areas of Hudson County, two branch centers were established in 1950 in towns where medical services were lacking or were inadequate. They are served by a dentist and are in charge of a resident internist, while services of other members of the clinic are provided on a rotation system. That these branches are being utilized is shown by their services to 1,873 and 1,577 patients, respectively, Dr. Esselstyn pointed out.

To make services available at a cost that 90 percent of the people could afford, a fee schedule was established about the equivalent of the fees paid by a full-rate patient of a free out-patient department in New York City. No means test has ever been applied and 24 months of credit are extended to those desiring time to meet their obligations. For medically indigent families, \$88,000 worth of free care has been provided by the dispensary. No person has ever been refused medical care for financial reasons, said Dr. Esselstyn.

Preventive medicine is one of the main purposes of the clinic. The cancer detection center, organized

at the request of the American Cancer Society in 1947 and the first in upstate New York, is today recognized by the American College of Surgeons as a tumor diagnostic clinic. An outgrowth of this work is an annual review program, offering thorough medical examination designed for the symptom-free well adult. While not widely accepted by the people in the county, three corporations are now arranging this program for their executives.

Initial Problems

The establishment of this organization has not been without difficulties, said Dr. Esselstyn. Among them has been community skepticism. Also, fellow practitioners resisted despite the fact that each man in the clinic is a replacement and not an additional physician in the area, and every effort has been made to maintain the confidence of the patient in the referring physician, and to keep the referring physician promptly advised on findings.

The clinic experimented with a percentage system of remuneration in order to include two local practitioners on its staff. It found that this basis of remuneration acted as a deterrent to ease of referral since it automatically set up competition between the members of the staff and also between its departments. As a result it produced the clinic's present policy, namely, that men of equal training who are devoting an equal amount of time and effort and have served an equal number of years should be paid in equal amounts.

Dr. Esselstyn also pointed out that the community was rapidly transferring from the dream of the general practitioner of the past to the realism of the well-trained internist of the present, who functions as the family doctor of today within the group structure. When this has been fully understood one of the misconceptions associated with group practice will have been eliminated, he said.

4,000 Longshoremen Get Multiphasic Screening

Multiphasic screening with organized medical follow-up of some 4,000 longshoremen in the San Francisco area was successfully accomplished as a result of the active cooperation of the International Longshoremen's and Warehousemen's Union, the labor-management welfare fund, the Permanente Health Plan, and a wide array of public and voluntary health agencies in the community. E. Richard Weinerman, M.D., M.P.H., medical director of the Permanente Health Plan at the time of the survey and now medical consultant of the San Francisco Labor Council, and his associates, reported.

A battery of laboratory and other tests screened presumptive cases for clinical follow-up in the group medical centers of the Permanente Health Plan, a prepaid health plan in which the workers were enrolled. Screening procedures consisted of medical history, chest X-ray, electrocardiogram, and tests for height and weight, vision, hearing, syphilis, hemoglobin, blood sugar, urine sugar, urine albumin, and blood pressure.

Associated with Dr. Weinerman in the study were Lester Breslow, M.D., M.P.H., chief, bureau of chronic diseases, Benno K. Milmore, M.D., M.P.H., acting chief, bureau of chronic diseases, and Nedra B. Belloc, M.A., associate statistician, morbidity research project, all of the California State Department of Public Health, and Anne Waybur, A.B., health educator for the union.

Diseases, Defects Found

Diagnostic evaluation of men with positive test findings revealed significant amounts of disease and defect not previously known or not medically controlled, the study showed. The most striking health problem of these men, the majority of whom were in the older age brackets, was obesity, which showed a significant correlation with hyper-

tensive disease and diabetes. Dr. Weirnerman pointed out that 35 percent of the men tested had one or more positive diagnoses. More than half of these, representing one-fifth of the total tested, had at least one newly discovered condition.

The estimated total cost of \$9 per person tested for the screening and initial follow-up was considered by Dr. Weirnerman to be modest in terms of the health values attained. Multiphasic screening combined with organized follow-up, which eliminates the economic barrier to medical service, was presented as a useful technique for positive health education, early detection of disease, timely application of medical care, and delineation of controllable public health problems.

Broad Indemnity Program At ACWA Health Center

Members of the Amalgamated Clothing Workers of America have been covered by a comprehensive hospitalization and surgical indemnity program since 1944, but to furnish them even broader medical services the union's New York Joint Board opened the Sidney Hillman Health Center in April 1951 in lower Manhattan's garment industry area, reported Morris A. Brand, M.D., medical director of the center.

In a six-story building where comprehensive clinical services are provided in a spacious, colorful, well-lighted, and unburied atmosphere, he continued, there are 34 examining and treatment rooms—including special suites for minor surgery, electrocardiography, radiology, cardiology, otolaryngology, physical medicine, and ophthalmology—60 dressing cubicles, and a clinical laboratory, a pharmacy, and a medical record room.

Although the center does not provide psychiatric treatment, dental care, or treatment for illnesses covered by workmen's compensation insurance, each member, upon payment of an annual 10-dollar fee, is

entitled to otherwise unlimited physicians' services. Additional nominal fees for treatments in physical medicine and for radiological and laboratory services were eliminated January 2, 1952. Approximately 33,000 union members and their wives were enrolled in the center at the end of 1952, Dr. Brand said, and 76.9 percent of those seeking services were 40 years of age or older.

During the center's first 18 months, he continued, its medical staff of 27 general physicians and 54 specialists provided 27,058 hours of service, 14,506 and 12,492 hours, respectively. All of them accept the ACWA Insurance Fund's surgical fees as their total fees for operations performed for the center's members.

Functional Hospitals Foster Improved Care

Hospitals must be architecturally functional if they are to provide adequate medical service to all who require it, maintained E. M. Bluestone, M.D., consultant at New York City's Montefiore Hospital. He told the joint meeting of the medical care section and the American Association of Hospital Consultants that flexibility of arrangement to permit continuing expansion of service is the absolute requirement of such construction.

Organized medical care is becoming increasingly better, Dr. Bluestone declared, and hospitals can lead in the progress through an expansion of both in-patient and out-patient facilities and services. But it must be an integrated expansion, he stressed; there can be no such line of demarcation between the two programs as a fixed hospital wall. He emphasized that medical care must not only be comprehensive and complete, but also must be continuous and sufficiently mobile as to be available to everyone, regardless of his urban, suburban, or rural location.

"Not Only the Sick"

To provide such extensive care, he continued, the hospital must treat not only the sick, but also the near and recently sick. Therefore, the medical, nursing, and social organizations of the hospital must be adjusted to the distinctive requirements of each group. A shift of emphasis by the hospital from the in-patient to the out-patient department, with attendant expansion of home nursing and social services, will reduce the demand on beds within the hospital, he said, but it will force the expansion of diagnostic, therapeutic, laboratory, and operating room facilities for they will have to serve beds outside as well as inside the hospital.

These are trends which the architect, as well as hospital trustees, should consider in planning suitably functional hospitals, Dr. Bluestone averred. He felt, however, that not only are few architects professionally equipped to survey accurately the present and future medical requirements of a community, but that many hospital executives also lack the ability to make such a study. Planning for medical care requires a working combination of both professional skills, he said.

Patient Choice Fosters HIP Group Competition

The vast majority of the 400,000 enrollees of the Health Insurance Plan of Greater New York "are convinced they are receiving the best medical care they have even known," Edwin F. Daily, M.D., deputy medical director of HIP reported to the medical care section.

Standards Are High

Medical care in HIP, said Dr. Daily, is provided only by physicians meeting the professional standards of the HIP medical control board. They work in groups, each group comprising at least 5 family physicians and a specialist from each of the 12 basic specialties of medicine

and surgery. Regular clinical staff meetings are required in each group, he continued, and emergency night and week-end calls are rotated among the members. Healthy competition between groups is maintained, he stated, since subscribers are free to change groups or family physicians within a group.

Centers Required

Each medical group must have a center with sufficient facilities for all ambulatory services by both family physicians and specialists, Dr. Daily said, as well as laboratory, X-ray, and special services such as electrocardiography, basal metabolism, and physical therapy.

All necessary medical care is provided for an annual fee per person paid to the selected medical group, Dr. Daily stated. After overhead and administrative costs have been paid, the remaining income is distributed among the physicians according to the formula of their particular group. "The capitation basis of payment . . . is a most important principle," he said, "relating fundamentally to the quality of medical care provided."

New subscribers are informed of the available services and the methods of using them, according to Dr. Daily, and are encouraged to discuss with their medical group directors any dissatisfaction with the plan and to offer suggestions for improvement. The subscriber service division at HIP headquarters receives all inquiries, complaints, and expressions of satisfaction with the plan. At meetings under the guidance of the HIP education staff the medical groups and their subscribers discuss subjects of mutual interest.

Medical Care Quality Reviewed

A study of the quality of medical care in all groups was made in 1949, Dr. Daily reported, and individual meetings were held with medical group directors and their staffs to review the findings. During the past year case histories of adults examined in several medical groups have been reviewed, he continued,

and statistical studies are continually under way "to detect any weaknesses . . . and to bring about improvements as rapidly as possible."

NYC Hotel Employees Have Modern Medical Center

Hotel employees in New York City were the first in the hotel industry to benefit by industry-wide group insurance, according to Frank P. Guidotti, M.D., medical director of the New York Hotel Trades Council and the Hotel Association Health Center, Inc., New York. Over \$5 million in benefits, including payments from life insurance, accidental death and dismemberment insurance, weekly accident and sickness benefits, and hospital benefits, were paid to beneficiaries and their families during the first 6 years of operation.

This program, known as the New York Hotel Trades Council and Hotel Association Insurance Fund, was created by the joint action of the Hotel Association of New York City, representing management, and the New York Hotel Trades Council (affiliated with the American Federation of Labor), representing labor, explained Dr. Guidotti. Ten local unions form the New York Hotel Trades Council.

Modern Facilities

On October 25, 1950, the New York Hotel Trades Council and Hotel Association Health Center opened a modernized 5-story building in mid-Manhattan to provide a comprehensive preventive medical program, diagnostic and specialist services, as well as in-hospital medical and surgical care to all hotel workers as of the first day of employment. The center's technical staff has 175 physicians (30 general practitioners and 145 specialists), 13 nurses, 4 laboratory technicians, 3 X-ray technicians, 2 physiotherapists, 2 pharmacists, 2 registered medical record librarians, and a registered medical social service worker.

The center encourages the relationship between patient and physician and cooperates with referring family physicians, Dr. Guidotti maintained. Patients are seen usually on the appointment basis. In addition to general medical services, optical examinations are offered, and counsel on social aspects of a patient's problem is given by the medical social service worker.

The health center maintains visiting nurses, blood bank services, and free ambulance service, said Dr. Guidotti. It distributes monthly information pamphlets on preventive medicine and health information; it recently established a pension plan for retirement benefits for hotel employees.

Care for 35,000

The health center provides care for 35,000 hotel workers, ranging in age from 18 to 85, who are employed in 177 New York City hotels and 51 concessions, representing 209 different occupations. Maids, waiters and waitresses, elevator operators, housemen, cooks, dishwashers, bellmen, busboys, and telephone operators are the most numerous employees.

Physician services per patient averaged 6.5 for the first year. Records showed the most frequent diagnoses to be:

	Number
Refractive errors-----	1,350
Hypertension and hypertensive heart disease-----	916
Acute upper respiratory infections-----	852
Allergic disease, including hay fever and asthma-----	576
Varicose veins-----	572
Arthritis-----	480

Funds are provided for this entire welfare program by an established percentage of the payroll of each contributing member-hotel. Cost of operation for the first year was \$600,000, approximately \$17 per capita, according to Dr. Guidotti. Medical services are provided without charge to eligible patients. Prescriptions are filled at cost by the center's pharmacy.

New and Developing Elements In Public Health Programs

That the dimensions and characteristics of public health are fluid and ever-changing is well illustrated in the foregoing summaries of major papers. By way of further illustration are the following summaries dealing with a miscellany of topics ranging from rheumatic fever to home safety and a critical examination of the health officer's job.

Test Indicates Absence Of Rheumatic Fever

Reporting that a low antistreptolysin-O (AST-O) serum level is highly reliable as a single diagnostic index of the absence of active rheumatic fever, Nell F. Hollinger, Ph.D., assistant professor of public health, University of California, said that if an AST-O serum level of 50 or less Todd units is obtained repeatedly for a child with a clinical diagnosis of active rheumatic fever, re-evaluation of other medical findings is indicated.

Dr. Hollinger reported the results of a 5-year study of the serums of 6,332 rheumatic and nonrheumatic children. Well children, or those with illnesses other than rheumatic fever, were grouped as nonrheumatic children.

Just as a negative tuberculin reaction confirms the absence of active tuberculosis, Dr. Hollinger said, a negative reaction to the antistreptolysin test might prove to be of considerable clinical worth in indicating absence of active rheumatic fever.

Determination of AST-O is a simple serologic procedure, reliable within accepted serologic limits, according to Dr. Hollinger. AST-O is

the antibody of streptolysin-O, a streptococcal product, and is present at some time in the serum of at least 90 percent of those who have had streptococcal infections. The antigen, streptolysin-O, is used to test for the presence of the antibody AST-O. The Todd unit of anti-serum is used as an arbitrary standard to test the neutralizing of new lots of antigen, she explained.

Clinical Values

Other significant conclusions reported by Dr. Hollinger include:

AST-O values presented in this study and others published over a 20-year period show that only 0.82 percent of 1,339 individuals with active rheumatic fever would have been misclassified as nonrheumatics if 50 or less Todd units were used as the diagnostic exclusion index.

A high AST-O serum level, over 250 Todd units, was found to be a misleading guide when used as a single diagnostic index of the presence of active rheumatic fever. On the basis of such an index, 19.4 percent of 5,135 nonrheumatics would be misclassified as active rheumatics; and 42.5 percent of 197 children with active rheumatic fever would be misclassified as nonrheumatics. A higher AST-O serum level of over 800 Todd units would be even more misleading since 88 percent would be classed as nonrheumatics; and 5 percent with illness other than active rheumatic fever would be misclassified as active rheumatics.

No universal pattern of AST-O serum levels was obtained for AST-O values tabulated as normal (well children), active RF (for children with active rheumatic fever), or clinic-nonRF (for children with illness other than active rheumatic fever). With the exception of normals for Texas, 30 percent of normal and clinic-nonRF AST-O values

for California, Colorado, North Carolina, Texas, and Vermont were found to be 50 or less Todd units.

Believe Hospital Contacts Spread Resistant Strains

Urging a halt to the practice of indiscriminate administration of antibiotics for a host of minor illnesses, three University of Illinois epidemiologists reported their observations on the epidemiological spread of antibiotic-resistant staphylococci among hospital patients, their contacts, and hospital personnel.

Presenting the report were Harry F. Dowling, M.D., professor and head of the department of medicine; Mark H. Lepper, M.D., associate professor, department of preventive medicine; and George G. Jackson, M.D., assistant professor of medicine and preventive medicine of the University's College of Medicine.

"The number of antibiotic-resistant strains in a given segment of the population presumably increases with the number of individuals who have received antibiotic therapy," they explained. "It would be profitable to explore techniques of managing patients under treatment with antibiotics so as to prevent as much as possible the spread of resistant strains via hospital personnel to other patients."

The investigators noted that the appearance of resistant strains has followed treatment with penicillin, but "often, perhaps more often, has been due to the spread of resistant strains to hospitalized patients from other patients and from attendants."

Cultures Studied

Drs. Dowling, Lepper, and Jackson investigated the sensitivity to aureomycin and penicillin of the staphylococci strains present in the noses and throats of patients discharged from the Municipal Contagious Disease Hospital, Chicago. Cultures were taken from the patients' household contacts and from

up for health protection of troops for possible assignment outside the country became the basis of a syllabus for public health officers in training for civil affairs.

Much early work of a public health nature in liberated areas was done by nonmedical health officers and engineers, he said. Even now, in reserve units, it is questioned whether enough medical officers in proper grade can be found to lead public health teams, he added.

World War II Experience

"We had only a hazy picture of the situation in occupied countries in late 1943," he said. "We were told that over a quarter of a billion people of varied cultural patterns, some enslaved for years, with millions virtually homeless, had been constantly subjected to pestilences, or to threats of epidemics of typhus, and bore emotional scars. They were reported to be either starving or hungry, and experiencing magnified problems of maternity and infancy, of tuberculosis and mortality from many causes.

"The military job in working with those unfortunate people had as a primary focus the military necessity to keep supply lines and communications open and to prevent disorder," he continued.

Dr. Hiscock added: "In fulfillment of this mission, efforts were aimed to help the people of liberated countries to help themselves in getting on their feet, with the idea of turn-over of military responsibility at the earliest practicable date."

As part of the public health program, the War Department established a policy to provide supervision of communicable disease control, of maternal and child health measures, of home and hospital nursing services, and for emergency care of sick and injured, he said.

Adequate Personnel

"Qualified personnel is of more significance than the form of organization. There is no single formula for each activity or region; and only

a flexible pattern with basic policies, principles, and techniques can be prescribed in advance. Detailed information concerning each country and region, implemented by practical guides as background, together with brief directives and essential supplies comprise the initial armamentarium required by the qualified civil affairs public health administrator," he said in quoting from a personal memorandum written in 1944.

Current manuals on military government regulations, Dr. Hiscock said, recognize that safeguarding the health of civilians and of occupying troops is vital to reestablishing a war-torn nation.

Health Officer's Job Needs Redefining

Public health activities should follow the needs of the times, and health officers should redefine their place in the community, said Berwyn F. Mattison, M.D., commissioner of the Erie County Department of Health, Buffalo, N. Y.

The definition of the health officer's field of a few decades ago no longer suffices, Dr. Mattison stated. Redefinition is needed to clarify health problems, the techniques for attacking these problems, and the effectiveness of the attack.

"More field studies are needed to establish quantitative relationships between disease and social factors such as age, race, sex, occupation, and economic status," the speaker continued. These factors and their impact on community disease patterns are the health officer's counterpart of the clinician's measurement of a patient's pulse, blood pressure, and basal metabolism, he said. He stated that much of the necessary information is available and that more attention should be given to the data and to their relationship to health and disease.

Barriers Against Disease

Four types of community-wide barriers against disease are avail-

able, the speaker stated. He described these barriers as physical—water filtration, milk pasteurization, air pollution control, and improved housing; physiological—widespread immunization programs, better nutrition, and fluoridation of water supplies; epidemiological— isolation, quarantine, vector eradication, and early case control; and educational—accident prevention, information leading to prevention and early recognition of heart disease and cancer, and promotion of health habits leading to improved physical, emotional, and mental efficiency.

Less emphasis on communicable disease control and more emphasis on positive programs relating to accidents, heart disease, cancer, diabetes, and the degenerative diseases of the elderly are needed today, Dr. Mattison said. More emphasis and less lip service should be given health education, the physician continued. The health officer should understand, direct, evaluate, and take full responsibility for this part of his program and, in addition, should participate actively in community activities, he stated.

Community Leadership

The health officer can provide leadership in his community by working actively for health councils or health committees in councils of social agencies, by teaching at professional, secondary, and elementary school levels, and by seeing that the subject of community disease and public health are well presented, according to Dr. Mattison. This cannot be accomplished, he said, on a 5-day, 40-hour week. "The best-trained health officer is of little value to his locality if his specialized skills are not readily available."

By developing standards for community and service record analysis that will be comparable for all communities, "we should be able not only to justify our current activities but to prognosticate changes in emphasis for the future," the health officer concluded.

Techniques in Health Statistics

And Records Management

Methods of following records of veterans to determine the outcome of their disease experience and the technique of covariance were subjects presented at sessions of the statistics section of APIA and the Biometrics Society. At joint sessions of the statistics section, the American Association of Registration Executives, and the American Association of Medical Record Librarians, panel discussions were held of the Census Bureau's post-enumeration survey, a survey of population trends, and the role of the medical record librarian in public health statistics.

Record Follow-Up Methods Developed for Veterans

The techniques developed in a pilot study, conducted for the Veterans Administration in 1948-50 by the Committee on Veterans Medical Problems, National Research Council, provide an efficient and systematic basis for exploiting the unique opportunities for record follow-up in the vast medical experience of armed forces personnel and veterans, reported Bernard M. Cohen, Ph.D., a statistician on the committee.

The committee's program was developed in two parts, the first being clinical studies. The second was record studies, which employed large samples to discover through existing records and by questionnaires facts of mortality, survival, hospitalization, and disability.

The pilot study collected considerable information on tracing and locating resources and on the nature

and value of the facts they can supply, Dr. Cohen said. These data were analyzed to gain more insight into the factors that enhance success in follow-up and to examine questions of completeness, validity, and bias.

He pointed out that in establishing rosters for study, identification of individuals represents a special set of problems. Usually, he said, service serial numbers are received without names, or names without numbers. For further processing, both are required, as well as confirmation that the individual received the diagnosis in question. When follow-up is initiated, files permit further verification of name, serial number, and often diagnosis.

A substantial portion of the observations sought came directly from the Veterans Administration, and the agency also provided most of the leads that resulted in successful tracing. Such additional resources as the Retail Credit Company, the American Red Cross, the Army, other Federal agencies, and private organizations were also used. A questionnaire to those located was especially useful in confirming current survival, in uncovering a few cases of wrong identification, in providing information on hospital admission not federally financed, and in indicating in general terms the health and work status of respondents.

Major Findings

According to Dr. Cohen's summary, the study showed that:

Satisfactory rosters can be defined for a wide variety of conditions and environmental hazards. The six rosters used included a syphilis group; Hodgkin's disease and scarlet fever groups, representing almost the extremes in morbidity and mortality expectations; diabetes and ulcer

groups; and a control group. The syphilis group was from World War I; the others, from World War II.

Identification by matching name, service number, and diagnosis can be accomplished in 96 percent of the cases.

Mortality and survival status can be determined for 99 percent of those identified. This percentage was demonstrated for World War II men approximately 4 years from date of diagnosis. For World War I men, the percentages decreased as the numbers of years from date of diagnosis increased, the lowest percentage being 89.7 after 30 years.

Data on hospitalization can be obtained for an estimated 94 percent of admissions. Veterans Administration records supplied 86 percent of the total admissions reported; the questionnaire, 73 percent.

Veterans Administration disability ratings can be obtained for every case; the veteran's own report of his work status, for 86 percent of the survivors. Comparison of VA disability ratings with clinical investigations of the patient's working capacity at the time of follow-up examination (part of clinical studies also conducted by the committee) indicates that the VA ratings can be used as rough measures of the disability aspect of prognosis.

Post-Enumeration Survey Checks Census Accuracy

The post-enumeration survey of the Census Bureau was described as a quality check on the accuracy of the 1950 census by William N. Hurwitz, M.A., the bureau's chief statistician.

If the major national aggregates for population, housing, and agriculture were the only characteristics to be measured, sample estimates would be more accurate and less costly than a census, Mr. Hurwitz explained. But a census is justified by the data it provides for small geographic areas or for cross-classifications of relatively few people, he said.

As a sample, the monthly current population survey could have been used as a concurrent quality check on the accuracy of the census, but this might have been construed as a "whitewash," and risk loss of public acceptance, he pointed out. Too, there was a possibility that comparing census and survey information for identical households might "condition" results, he said, leading to understating the differences between the census and the sample. As it was, a current population survey, conducted during the census period, checked on only one characteristic—the labor force participation of the population—a changing attribute which could not have been checked following a census, he said.

Post-Enumeration Survey

As a post-census survey, the PES checked on census accuracy in: coverage, age and income distribution, pattern of educational attainment, tenure status of dwelling units, and uses of farm acreage, Mr. Hurwitz reported. It sought to determine if the additional cost of discovering errors were justified, he indicated.

Steps were taken to improve the quality of the PES over the census: the best qualified interviewers and supervisors were trained intensively; they were paid hourly rates to avoid report padding or omission of isolated households; they were instructed to select the best respondent in a household rather than the available respondent, he continued.

PES measured errors in the recording of data and errors of undercoverage and overcoverage. "Any fears that errors of overcoverage due to padding might be substantial were not well-founded for they amounted to less than 0.1 percent of the total people enumerated in the population census," Mr. Hurwitz stated. "This emphasizes the importance of using objective methods for studying sources of errors, rather than relying on impressions," he said.

According to the PES, the net omission rate of persons from the census in enumeration districts

where they should have been enumerated was only 1.4 percent plus or minus 0.2 percent, or about 2 million people plus or minus 340,000, he also stated. "As between urban and rural classes, the under-enumeration seems to be greater in the very large cities and the more rural areas," he added.

Checking the PES

By "checking the cleeck," census statisticians learned of errors in designing PES and in processing results. Interviewers had missed dwelling units. The numbers of missed persons classified by age did not agree with other evidence, he reported. For example, PES findings for missed children under 10 did not agree with an analysis of birth and death statistics for the period 1940-50, he said.

New techniques of treating future under-enumeration problems can come from knowing that about two-thirds of the persons erroneously omitted from the census were in households never included. About a third were missed within enumerated households, mostly among nonmembers of the immediate family, he said.

Mr. Hurwitz described the introduction of "record checks"—using income tax returns, social security records, earlier census reports, industry wage reports, Veterans Administration records to get evidence on the comparative accuracy of response in the PES and the census. "Presumably more accurate information is contained in such records," he stated. All dubious matches are discarded and the balance of matched records is used to draw inferences about errors.

Analysis of Covariance In Analytical Surveys

The analysis of covariance is proposed by B. G. Greenberg, Ph.D., associate professor of biostatistics, University of North Carolina School of Public Health, as a superior alterna-

tive to the usual "adjustment" (for age, sex, etc.) methods used in public health and vital statistics.

The statistical technique is derived from the statistics used in biological and agricultural experiments. Items for which adjustment is usually made are called covariates. Covariance analysis is an extension of regression techniques, associated with the analysis of variance, he said.

According to Dr. Greenberg, the major advantage of the covariance technique is that it enables the researcher to use data more fully. For example, the common adjustment techniques, as for age, require setting up arbitrary groupings even though the data may really be continuous. It is also possible to make proper statistical significance tests using the covariance technique, while there are difficulties in significance testing with adjusted data.

Balancing Technique

Dr. Greenberg also discussed a technique for achieving some of the results given by covariance analysis through balancing of the individuals in an experiment with respect to the covariates. Generally, in public health problems, balancing, or matching, does not achieve results as good as covariance analysis, he said.

He described a development showing that if the study consists of "less than 10 subjects on two treatments, a slight gain in efficiency may be obtained by the technique of balancing." For larger sample size there is little or no gain.

Some limitations in the use of covariance analysis were also discussed by Dr. Greenberg. In addition to the usual assumptions underlying the analysis of variance which are also the assumptions underlying the usual t-test, covariance techniques introduce three further assumptions: linearity of the relation between the covariate and the variate being investigated; equality of regressions in the two groups being studied; uniform variances in the variate studied at different values of the covariate, the usual assumption

of equality of variances in regression problems.

Extension of covariance analysis to more than one covariate was outlined by Dr. Greenberg.

Population Data Valuable In Determining Needs

Recognizing the importance of population data to public health departments, as a means of determining community needs for health services and as the denominator for the computation of vital rates, Mortimer Spiegelman, an associate statistician of the Metropolitan Life Insurance Co., presented a brief survey of population characteristics and trends to a joint session of the statistics section with the American Association of Registration Executives.

Among the points he noted were these:

Age—Perhaps the most significant change during the last decade was the great increase in the number of children, resulting from the war and postwar upsurge in birth rate.

The age group 5 through 19 years increased barely 2 percent between 1940 and 1950, but the present decade will see an increase of about 30 percent.

The age group 20 through 44 years will probably increase by only 2 percent by 1960, but after this date, the group will grow rapidly. Another upswing in the birth curve is expected then.

The population group aged 45 through 64 years will increase by about 18 percent from 1950 to 1960; the number in the age group 65 years and over is expected to increase by about 25 percent.

Sex—At ages 45 and over there were 97 females for every 100 males in 1940, but in 1950 there were 105 females per 100 males. By 1960, the number may mount to as high as 113, thus increasing the problems resulting from widowhood and dependency.

Family—A tendency toward earlier marriage is evidenced by the

increase in the percentage of girls aged 18 and 19 years who are married—from 22 percent in 1940 to 32 percent in 1951.

There were 26 percent more married couples in 1951 than in 1940. The trend toward an increase in the number of families (all groups of two or more related persons living together) and in the number of households and a decrease in the average size of families and of households is likely to continue. However, there is some indication that the long-term downward trend in the average size of completed family, generally defined as the number of births per mother of completed fertility, may have been halted.

Labor force—Industrial health services must be geared to the needs of a growing labor force, an aging labor force, and one that includes an increasing proportion of women workers.

Income—The average family income in 1950 was \$3,300, over 25 percent greater than in 1945. In general, a high average income means not only a better state of health, but also a higher grade of medical and hospital care. Thus, the health department can give proportionately less effort to communicable disease problems and more to chronic diseases.

Education—The task of public health education is great, but the job is being speeded by the rising educational level of the American people. From 1940 to 1947, the proportion of persons 21 years old and over who had completed secondary school rose from one-fourth to more than one-third, and the outlook is that the proportion will rise to more than one-half by 1975.

Migration—The movement of the population to urban places is continuing, bringing an increasing proportion of the population within range of the activities of the public health department. The accompanying shift of the urban population to suburban areas has, however, required an expansion of public health activities.

Urges More Censuses

One of the discussants of this paper, Henry S. Shryock, Jr., Ph.D., assistant chief, population and housing division, U. S. Bureau of the Census, maintained that more frequent population censuses seem the only real answer to community needs.

Dr. Shryock also added a few supplementary facts regarding national population characteristics. He noted that the 2-percent increase cited for children aged 5 through 19 years marks some very divergent changes among the various ages included—an increase of about one-quarter for those aged 5 through 9 years; a decrease of about 4 percent for those aged 10 through 13 years; and a decrease of about one-eighth for those aged 14 through 19 years.

He also mentioned that the marriage rate leveled off in 1952.

Role of Hospital Librarians In Public Health Statistics

The forces bringing hospitals and health departments closer together were noted in a panel discussion of the role of the medical record librarian in public health statistics. This session was moderated by William Haenszel, M.A., director of the bureau of vital statistics, Connecticut State Department of Health.

Responsible for this closer producer-consumer type relationship between hospitals and health departments is the increasing amount of public health data that is available only from hospital records, the participants indicated. The growing practice of locating health department offices adjacent to or even in hospital buildings was pointed to as a visible sign.

Participants in the panel discussion at a joint session of the statistics section, the American Association of Registration Executives, and the American Association of Medical Record Librarians were: James G. Harding, M.H.A., superintendent, Cleveland Clinic Hospital, Marjorie R. Quandt, B.A., director, medical

record department and school, Wesley Memorial Hospital, Chicago; Matthew Taback, A.M., director, bureau of biostatistics, Baltimore City Health Department; and M. Loyola Voelker, B.S., director of medical records section, Public Health Service Hospital, Baltimore.

The panel pointed out, however, that public health statistics are also the concern of hospital associations, medical societies, voluntary health agencies, and schools of medicine and public health. It was stressed that health departments have the responsibility of integrating their requests for hospital data with those of other organizations to ease the burden placed on hospital administrators and record librarians.

Each year, the proportion of births and deaths occurring in hospitals continues to grow in all sections of the country, making the hospital the source of more of the birth and death certificates filed. In the control of chronic diseases, health departments require data now available only in hospital records. With the breaking down of the boundaries between preventive and curative medicine, hospital data will become increasingly important to health departments, the panel brought out.

Clearance of Reports

To achieve completeness and accuracy of reporting, it was suggested that the medical record librarian review and clear all reports submitted to outside agencies. The medical record librarian should be able to establish controls on the receipt of all requests for information, to follow up on their disposition in compliance with hospital practice, and, especially, to check on the quality of information furnished, it was stated.

Although the librarian cannot be expected to obtain all information, it was repeatedly stressed that one of her prime functions was to edit and spot check the reports for accuracy and maintain their quality.

The need for a clearing center was highlighted by a study of the record-keeping procedures in Baltimore hos-

pitals for completing the birth certificate medical supplement. It was found that one or a combination of four types of personnel—obstetrical secretary, resident, or nurse, and attending physician—performed this job. None of these persons had a primary interest in record keeping. Furthermore, the turnover of nurses in residence and the haste of the attending physician contributed to an instability of medical record keeping.

Panel Suggestions

During the discussion, the following suggestions were made:

1. Close cooperation between public health statisticians and medical record librarians is needed. National organizations should appoint committees for combined exploration of their problems, but most of the work should take place on the local level. Local organizations should sponsor workshops and training institutes. Health department statisticians should visit the hospital personnel.

2. Since the academic statistical training of medical record librarians is sketchy, health departments might attain long-run benefits by sponsoring in-service training for medical librarians in elementary statistical principles.

3. State health departments might find it profitable to employ medical record librarians as consultants to assist local health departments in strengthening liaison arrangements with hospitals.

4. Bureaus of vital statistics should send requests for additional clarifying information on hospital births and deaths to the medical record librarian rather than directly to the physician.

5. Health departments should supply hospitals with tabulations and lists of births and deaths occurring within individual hospitals. So far, transmission of data has resembled a one-way street. Tabulation of data of interest to the hospital would stimulate its interest in seeing that the health department receives needed data.

6. A medical record librarian

should lead in educating the medical staff on the importance of reports submitted to health departments by means of orientation lectures to residents and interns, participation in the medical record meetings, and informal instruction.

7. The general acceptance of uniform standards among States on reports required from hospitals, would benefit operations.

8. Health departments should take the initiative in getting together with other users of hospital data to eliminate duplications from their requests and to agree on standard definitions of terms. They should give advance notice of their requirements for an ensuing year and eliminate reports no longer useful or productive.

Hospital Stay Tables Similar to Life Tables

Consideration of some of the inadequacies and limitations of current indexes of hospital stay has suggested the adaptation of life table methodology to hospital statistics, declared Morton Robins, M.P.H., chief, and Rose Sachs, statistician, biometrics section, department of medicine and surgery, Veterans Administration.

The length of stay of patients in hospitals is a major concern of hospital administrators and statisticians, they pointed out. Hospital stay tables similar to life tables in concept and form are designed to present a dynamic and integrated picture of both the hospitalization requirements and the discharge experience of a group of admissions at significant points in time subsequent to their admission.

Outlining two methods of deriving hospital stay tables, they noted that these tables can usually be accomplished within the framework of existing hospital records systems. The employment of hospital stay tables and other biometric techniques can do much to improve and extend the utilization of hospital statistics, they concluded.

Rehabilitation in the Hospital

By HOWARD A. RUSK, M.D.

IN THE PAST, the physician too often has thought only about the physiological and clinical aspects of a patient's disability. The vocational counselor too frequently has considered only the physical skills which could be utilized vocationally. Between the completion of medical care and the beginning of vocational training, however, there is a wide area through which most physically handicapped persons must go. In this area lies the physical retraining in skills necessary for carrying on the activities inherent in daily living and common to all types of work.

Except in a few isolated instances, the physically handicapped person must be retrained to walk and travel, to care for his daily needs, to use normal methods of transportation, to use ordinary toilet facilities, to apply and remove his own prosthetic devices, and to communicate either orally or in writing. These are such simple skills that they are frequently overlooked, but the personal, vocational, and social success of the handicapped person is dependent upon them.

Some outstanding rehabilitation programs in various parts of the world have demonstrated that rehabilitation to the point of self-care and even to full or limited employment is possible

for many of the chronically ill who have been hospitalized for long periods. In most of our hospitals, however, the patient receives few services of this type. Hospitals complain that the chronically ill are responsible for their overcrowding, but they do little to provide the retraining services that will permit many of these patients to leave the hospital.

Survey of Hospital Rehabilitation Services

In 1951, the Commission on Chronic Illness in cooperation with the American Hospital Association sent out questionnaires to approximately 2,600 general hospitals of 50 beds or more to learn more about the problems of caring for long-term patients in general hospitals. Hospitals were asked if they had an organized rehabilitation service. For survey purposes "an organized rehabilitation service" was defined as a service which (a) studies patients with residual handicaps or disabilities due to illness or accident and (b) provides training and therapy to help the patient to adjust to, compensate for, or overcome the disability.

Among the first 1,600 hospitals responding, only 65 reported that they operated organized rehabilitation services. Only 18 of these reported that they had separate ward services with a specific allocation of beds for rehabilitation, and in many of these the services cannot be termed truly comprehensive. In the other 47 hospitals, rehabilitation patients were not segregated. Staffs ranged from those including full-time physicians specially trained in physical medicine and rehabilitation, physical therapists, occupational therapists, speech therapists,

Dr. Rusk, chairman of the department of physical medicine and rehabilitation of the New York University-Bellevue Medical Center, New York City, is an associate editor of the New York Times and chairman of the Health Resources Advisory Committee of the Office of Defense Mobilization.

vocational counselors, social workers, and others to those consisting of only a physical therapist and a social worker or a physician and a physical therapist. It was significant that 23 of the 65 hospitals reporting such services were hospitals of less than 250 beds.

Services in New York

The first comprehensive in-patient rehabilitation service in any general hospital in the United States and, to our knowledge, in the world was started at Bellevue Hospital in 1946 under the professional direction of the department of physical medicine and rehabilitation, New York University College of Medicine. Prior to the opening of this department, with a grant from the Baruch Committee on Physical Medicine and Rehabilitation, there was but one physician trained in this field on the staff of this 3,000-bed hospital. The hospital had a limited staff of registered occupational therapists, but physical therapy was administered primarily by unqualified "physical therapists" who had had little or no formal training. There were no registered physical therapists, no speech therapists, no rehabilitation counselors, no psychologists, no recreation specialists.

At present at Bellevue Hospital, there are 154 beds for rehabilitation: 69 beds for adults, 20 beds for children, and 65 beds for tuberculosis rehabilitation. At Goldwater Memorial Hospital, there are 200 rehabilitation beds; at City Hospital, 56 beds; at Kings County Hospital, 20 beds; and at Metropolitan Hospital, 30 beds.

The program will be expanded in the next 2 years by the opening of 22 beds at Fordham Hospital, which will be transferred to the Bronx Hospital Center when it opens. The number of beds at Queens General Hospital will be increased from 30 to 40, and the number at the Bird S. Coler Hospital will reach 400. The Bird S. Coler Hospital will then absorb the units now operating at Metropolitan and City Hospitals.

This expansion of rehabilitation services is a follow-up of the recommendations of the Hospital Council of Greater New York. In its master plan in 1947 the council suggested that 25 percent of the city's general hospital beds be allocated for convalescence and rehabilitation.

This would mean one such bed for each 1,000 of the city's population.

Organization and Operation

Physical medicine and rehabilitation in these hospitals is organized as a "service" department, usually operating in relation to the other hospital services in a manner similar to that of the X-ray or the laboratory department. For example, in Bellevue Hospital the rehabilitation service provides consultants for such other major services as fractures, pediatrics, surgery, and neurology. Its resident and visiting staff regularly make rounds with the resident and visiting staff of these services. Its staff may, *for example, see a patient in consultation before his leg is removed, indoctrinating him as to what he must expect, why he cannot keep his stump on a pillow, why he has to lie on his abdomen.* Medical responsibility during the period of definitive care, of course, rests with the initial or admitting service. As soon as the stitches are removed, the patient is transferred to a rehabilitation ward. At this time, the rehabilitation service assumes the major responsibility for his care, fitting of the prosthesis, and training in its use. The roles are now reversed; the surgical service has become the consulting service.

Prior to actual transfer of the patient to a rehabilitation ward, however, he attends one of the rehabilitation service's semiweekly evaluation clinics, where his problem is analyzed and discussed by all members of the staff—physical therapists, occupational therapists, nurses, vocational counselors, speech therapists, social workers, and psychologists—as well as the resident and visiting medical staff. The decision as to the feasibility of transferring the patient to the rehabilitation service is then made on the basis of the service's ability to contribute to his over-all physical, emotional, social, and vocational rehabilitation.

The rehabilitation services in New York City hospitals are unique in their scope of service, for they are among the few in the Nation, other than those operated by the Veterans Administration and some specialized facilities, which provide speech therapy, rehabilitation nursing, vocational counseling and job placement assist-

ance, psychological services, and a special therapeutic recreation program in addition to medical services, physical therapy, occupational therapy, and social services.

Economic Savings

Although it is difficult to estimate the financial savings to the city of such comprehensive rehabilitation programs, the 1951 experience of Goldwater Memorial Hospital gives some indication of how much these savings may be. In 1951, the 100-bed rehabilitation unit (increased to 200 beds in 1952) in this 1,500-bed hospital discharged 168 patients, some of whom went to other institutions but 91 of whom returned to their homes. Past experience indicates that each of these patients would have stayed at least one more year in Goldwater and many would have stayed much longer. At present hospital costs, the upkeep of these patients for one additional year would have totaled \$237,000.

Of the 91 patients returning to their homes, 12 were placed in full employment by the hospital's rehabilitation counselor working with other community agencies. An additional five patients were placed in part-time employment, and three were placed in sheltered workshops.

The amount listed above was not, of course, a net saving to the city, as the additional cost for physicians, therapists, and other personnel for the rehabilitation unit was about \$100,000 for the year. The additional cost cannot be charged entirely to the rehabilitation program, however, since these physicians and specialists also provided definitive services for the entire hospital.

Substantial savings accrue also from the lowered cost of care for patients who, as the result of rehabilitation training to the point of self-care, are transferred to the City Home and Farm Colony. The patient-day cost at the colony in 1950 was \$3.25 as compared with \$7.15 at Goldwater.

Similar economic savings were made through the organized rehabilitation units at Bellevue Hospital, which discharged 264 patients; at Metropolitan Hospital, which discharged 71; and at City Hospital, which discharged 135. The human value of these services, of course, cannot be measured by money.

Further evidence that this approach pays off economically and socially can be found in the

first year's experience of such a program on the chronic wards of Grasslands Hospital at Valhalla, N. Y. The original outlook for the majority of the 58 patients participating was continuous, indefinite hospitalization. Many had been in the hospital for months; some for years. At the end of the study, half of the group were walking without help and two-thirds had been discharged to their homes. Most significant was the fact that two-thirds required less than 60 days of rehabilitation training to make them self-sufficient.

Similar results have been reported at the Veterans Administration Los Angeles Center in a study of 105 patients, a typical group of elderly persons with declining or nonexistent economic potentials. All were physically disabled; a large number were chronically ill, many having histories of long periods of hospitalization prior to referral for rehabilitation. For various reasons, rehabilitation training was discontinued in 29 of the patients. Of the 76 completing their training, 34 were discharged to their homes, and the remaining 42 were transferred to the center's domiciliary unit, as they were ambulatory and capable of complete self-care.

From an economic standpoint, each of those discharged to their homes represents a saving of \$15.08 per day. Costs of maintaining those transferred to the domiciliary unit were reduced from \$15.08 to \$3.04 per day. Based on the 1950 Veterans Administration in-patient operating costs per day, the cost of providing care for the group of 105 patients at the time of their referral for rehabilitation was approximately \$1,583 per day. At disposition, the cost per day of caring for those remaining at the Los Angeles Center amounted to \$378, a reduction of over 300 percent, or an annual saving of approximately \$440,000.

In November 1950, a physical medicine and rehabilitation department was established at Gallinger Hospital in Washington, D. C., as a joint undertaking of the Public Health Service, the District of Columbia Office of Vocational Rehabilitation, and the District of Columbia Health Department. During the year prior to the formation of this new department, orthopedic patients spent an average of 55 days in the hospital. With the new program, the length

of hospital stay of orthopedic patients was reduced to 33 days, a saving of \$122,000 for orthopedic patients alone, based on a patient-day cost of \$12.50.

Experience has shown that the cost of additional specialized rehabilitation personnel largely offsets the over-all savings resulting from dynamic training programs for patients with chronic illness and rehabilitation patients who need fewer special services, such as drugs, dressings, operating rooms, X-rays, laboratory, and anaesthesia. The great saving results from the reduction in the length of hospital stay and the enabling of patients to return to lives of economic productivity or to care for themselves.

The Future

The hospital of today is being recognized

more and more as the focal point in public health activities. With the changing demands being placed upon it because of the growing incidence of chronic disease and disability, it must also play a more important role in the rehabilitation of patients. In the past, hospitals have concentrated almost solely upon the definitive aspects of medicine and surgery. If the hospital is to meet the changing health needs of the public, it must assume greater responsibility for all three phases of health: prevention, definitive treatment, and rehabilitation. As Bayne-Jones has said, ". . . they must become increasingly houses of prevention instead of houses of pity." The problems of chronic disease can be met only by the creation and utilization of abilities, not merely by the building of facilities.

The Visiting Scientist Program

The Public Health Service visiting scientist program established at the National Institutes of Health has been expanded to include research workers with demonstrated ability and specialized training. The plan, which permits the visiting research workers to conduct their investigations in the laboratories at Bethesda, Md., has been formalized in preparation for the opening of the Public Health Service Clinical Center.

The visiting scientist and the research associate are the two categories of visiting investigators. Requirements for the first category are a doctor's degree or its equivalent in training and experience, at least 6 years of postdoctorate research, and demonstrated ability in a specific research problem. Research associates must have the same training and experience, but not necessarily the same degree of identification with a specialized field.

Already among the guest scientists are Nobel Prize winners Albert Szent-Györgyi, Bernardo A. Hussay, and Otto H. Warburg. The first visiting scientist to be appointed under the new program is Dr. Horace A. Barker of the University of California, an investigator in the field of metabolism.

Occupational Factors in Lung Cancer

—A Preliminary Report—

By LESTER BRESLOW, M.D.

ONE OF THE MOST striking disease phenomena of the past two decades is the sharp increase in deaths due to lung cancer. The age-adjusted mortality rate for lung cancer in the United States climbed from 2.7 per 100,000 population in 1930 to 11.0 in 1948, a more than fourfold increase.

This higher rate is not a mere statistical artifact due to improved recognition of the disease. The lung cancer rate has increased two and a half times more rapidly among men than among women. It is highly unlikely that diagnostic improvements have been applied two and a half times more completely to men than to women. Furthermore, the increasing proportion of lung cancer found as a cause of death among autopsies in hospitals also attests to a real increase in this disease (1).

Lung cancer has become largely a disease of men. The age-adjusted mortality rate among males in the United States in 1948 was 17.5 per 100,000 population, nearly four times as high as the female rate of 4.6. Among males aged 45 to 64 years, lung cancer caused 3.1 percent of all deaths that year (2). If present trends continue, it will soon exceed tuberculosis as a cause of death among males in the United States.

Dr. Breslow is chief of the bureau of chronic diseases, California State Department of Public Health. He recently served as director of study for the President's Commission on the Health Needs of the Nation.

It is reasonable to assume that some change or changes in the environment account for this phenomenon. In such a hypothesis it is necessary to take into account the fact that our knowledge of carcinogenesis in man indicates a long latent period. Hence, an increase in the lung cancer mortality rate during 1930-48 may reflect environmental changes during the period 1900-40.

Evidence has already been accumulated which indicates an association between lung cancer and excessive cigarette smoking (3-6). Certain occupations, especially those involving exposure to chromate ore (7) and radioactive minerals (8), have also been implicated in the causation of lung cancer. However, the number of persons with such occupational exposures in the United States is relatively small.

Collection of Data

In an effort to get further data on the etiology of lung cancer, the California State Department of Public Health has investigated the occupational and smoking history of a group of lung cancer patients and of a control group.

The first group was composed of persons with histopathologically proven lung cancer in nine California hospitals. For every cancer patient, a patient of the same age, sex, and race admitted to the same hospital at about the same time for any condition other than chest disease or cancer was admitted to the control group. Thus, the lung cancer series and the control series were equated as to age, sex, and race. They were

Table 1. Number of patients with 5 or more years' exposure in randomly selected occupations among 408 lung cancer cases and 408 controls

Occupation	Lung cancer cases	Controls
Total-----	98	88
Hotel and restaurant managers----	5	5
Bookkeepers and cashiers, except bank cashiers-----	5	2
Salesmen, real estate-----	4	7
Bartenders-----	5	7
Guards and watchmen, except crossing watchmen-----	9	15
Animal and livestock farmers----	4	5
Gardeners and grounds keepers----	6	11
Electricians, skilled-----	6	6
Brakemen, railroad, skilled-----	9	3
Drillers, extraction of minerals and construction, skilled-----	6	2
Route men, semiskilled-----	9	8
Construction occupations, unskilled-----	30	17

also roughly equated as to socioeconomic status since both groups contained the same proportion of patients admitted to county-indigent, Federal, teaching, and private hospitals.

Each patient was questioned about the type and amount of his smoking and was asked for a detailed occupational history. The scope of the occupational data is indicated by the fact that each interview covered the patient's life-long history, required from 1 to 3 hours, and was conducted by a qualified occupational analyst.

Analysis of Data

Preliminary analysis of the data for 408 lung cancer cases and 408 controls confirms the association between excessive cigarette smoking in lung cancer identified in previous studies.

Preliminary analysis of the data implicates several occupational exposures not previously identified. A total of 59 occupations were listed five or more times by either cases or controls, or both, with a history of at least 5 years' exposure. The 12 occupations listed in table 1 are a random selection from these 59.

The five occupations listed in table 2 were selected by the observations, first, that the number of lung cancer cases exceeded by several times the number of control cases, and second,

that a common exposure among the five occupations appeared to be certain metal fumes and particles. The welders were arc and acetylene welders. The cranemen and derrickmen specified in their histories that they had worked on operations involving molten metals with consequent exposure to accumulated metal fumes. The majority of the firemen had worked in connection with either ships' boilers or industrial boilers. Although there were approximately equal numbers of miners with exposure to only gold and silver in both the group of cancer cases and the control group, the number of miners exposed to copper, lead, or zinc mining in the lung cancer group exceeded the number in the control group, indicating some association of this occupation with lung cancer. Likewise, tool dressers and drillers in oil-drilling operations appear more frequently in the series of cancer cases.

Although the numbers involved for the individual occupational groups are small, tests of significance showed that for cranemen and derrickmen exposed to metals the differences observed between cases and controls would be unlikely to occur by chance ($p < .05$) in repeated samples from the same population; for firemen (marine and stationary boilers) the observed differences also would be unlikely to occur by chance ($p < .01$).

Differences observed for welders, metal miners (copper, zinc, and lead), and tool dressers and drillers could occur by chance more frequently than the generally accepted level of statistical significance ($p > .05$).

Table 2. Number of patients with 5 or more years' exposure in selected occupations among 408 lung cancer cases and 408 controls

Occupation	Lung cancer cases	Controls
Total-----	40	8
Welders-----	8	2
Cranemen and derrickmen, exposed to metals-----	5	0
Firemen, stationary and marine boilers-----	11	1
Metal miners, copper, lead, and zinc-----	9	3
Drillers and tool dressers, oil-----	7	2

It is extremely unlikely that the observed difference for the total group would occur by chance ($p < .0001$); hence it is deemed to be significant.

Conclusion

This exploratory study was intended merely to identify occupations that have a suggestive association with lung cancer. The five occupations shown in table 2 are of this character. These occupations and the individuals so employed should be studied intensively in order to determine the exact nature of the relationship to lung cancer.

Suggestive differences have also been noted in this preliminary analysis with respect to other occupations; these likewise deserve further study.

Traveling Sanitation Classes

HAWAII. Usually students have to travel to the classroom, but in the school for food service personnel conducted by the division of sanitation, Territorial Department of Health, the classroom is brought to the students.

A sanitation education representative packs up his demonstration materials and conducts the course in a restaurant if it has more than five employees. Time for class is arranged for the employees' convenience to assure attendance, but managers or owners are required to be present also. Other classes are held in neighborhood restaurants for those places employing less than five food handlers.

Each restaurant receives an official inspection sheet and a printed form for posting on a bulletin board. Any employee discovering an insanitary condition inserts the nature of

the defect, recommendation for correction, his name, and date on the form. If the personnel and management are alert, and the sanitarian fails to find any defective conditions on his next inspection, the proprietor and employees win the game. Through the school and its encouragement of self-inspection, food service employees have become more conscientious about their work and are eager to seek advice, information, and suggestions.

Mercurial Diuretic Service

SHELBY COUNTY, TENN. The Memphis-Shelby County Health Department has proved the value of a nursing service for injecting mercurial diuretics into cardiac patients in their own homes. The program also affords opportunity for education in cardiovascular disease. It is planned to conserve the patient's energy and result in less frequent hospitalization and less crowded clinics.

At the present time, 65 percent of the nursing load is carried by district public health nurses. Registered practical nurses visit patients

in areas where a heavy concentration of cases makes it difficult for the district nurse to assume this emergency-type service.

Each cardiac patient is carefully evaluated at an out-patient clinic prior to referral to the nursing staff. Specific written instructions on medication accompany the referral. The majority of patients receive the injections weekly although treatment intervals may vary from daily to monthly. Patients return to the clinic for reevaluation whenever necessary.

The service was initiated in March 1950 by request of the Medical College of the University of Tennessee and the John Gaston teaching hospital. A brief preliminary institute on cardiovascular diseases was held by the medical staff of the college for the health department nurses. In the early experimental phase of the project, specialized nursing service was used with the idea of gradual absorption into the general program.

By May 1952, almost 800 patients were receiving the service, and more than 22,000 home visits had been made. Under supervision, the practical nurses have handled the service well.

Venereal Disease Contact Investigation

—A Combined Military-Civilian Program—

By NICHOLAS J. FIUMARA, M.D., M.P.H., JACK SEGAL, M.D., and JACK JOLLY, B.S.

THE CONTROL of venereal diseases among military personnel is a joint function of military and civilian authorities. A military program aimed at the prevention and control of venereal diseases will be effective only to the degree of joint participation of the civilian and military partners. Each group must assume responsibility in certain areas, but the program should be integrated in its conception and execution. A brief review will delineate the areas of responsibility of both the civilian and military authorities.

Military Program

The activities of the armed forces may be conveniently divided into two phases—the program for prevention and the program for control of the venereal diseases.

Preventive Program

1. Education. The objective of this part of the program is not only to motivate the individual serviceman to avoid exposure but also to strengthen and reinforce his belief in the fundamental truths of decency and morality, to

the end that he may retain his own self-respect, attain a mature and balanced personality, and build a sound basis for marriage, family life, and constructive community life. The character guidance program has been devised to accomplish this purpose.

2. Prophylaxis. Mechanical, chemical, and antibiotic methods of prevention are available for those servicemen who, for one reason or another, expose themselves to possible infection. They fail to appreciate the inherent limitations and effectiveness of these measures. Because of the conditions under which they are used—the inopportuneness, the messiness, the alcoholic inhibition factor, the time factor—these and many other considerations, it is imperative to de-emphasize prophylactic measures as a major part of the preventive program.

3. Measures are taken to maintain morale through effective leadership, a thorough understanding of the over-all objective of the services (why we are fighting), a fair distribution of the work, proper job placement and utilization, and adequate recreation.

Control Program

Control measures are designed to detect and treat cases of venereal diseases as soon as possible after they are contracted. The control principles used by the military authorities are similar to those used in civilian practice:

1. Screening tests through periodic examination of the serviceman.

2. Voluntary reporting to a medical officer should a serviceman suspect that he may have acquired a venereal disease.

Dr. Fiumara is director, division of venereal disease, Massachusetts Department of Public Health, and lecturer, Boston University School of Medicine; Colonel Segal is commanding officer of the U. S. Army Hospital, Fort Devens, Mass.; and Mr. Jolly is health program representative for the New England Area Regional Office, Public Health Service.

3. Contact investigation, to elicit the names, addresses, and circumstances surrounding each exposure with all contacts and with those persons exposed by the patient, within the maximum incubation period of the disease, from date of onset of the patient's symptoms to the moment treatment could be expected to be effective (1). Contact investigation also aims at the re-education and orientation of the patient.

Complementary Civilian Program

The civilian program, like that of the military, can be divided logically into two phases—measures aimed at prevention and at control.

Preventive Program

1. The civilian community is responsible for seeing to it that by the time an individual has reached military age, he has, through proper home training, religious instruction, and community socialization, developed a mature and balanced personality and a self-disciplined character.

2. The repression of commercialized and clandestine prostitution is the responsibility of civil law enforcement authorities (2).

3. The civilian community should also provide an environment, during the off-duty hours of military personnel, which is not only safe and wholesome, but which integrates the recreational and social activities of the servicemen with those of the community's civilian components.

Control Program

1. Participation of the civilian health department in the military venereal disease control program implies that the former maintains and operates an efficient and well-ordered venereal disease control program. This should include adequate case-finding, diagnostic, treatment, and case-holding procedures for the venereal diseases for the civilian population (2).

2. Contacts of military personnel should be investigated with dispatch. Once these contacts have been found and examined, a report of their medical disposition should be forwarded without delay by civilian health departments to the proper military authorities.

3. Military personnel who are contacts of in-

fectured civilians should be reported to the appropriate medical commands of the military services, and the results of the medical examination of the named servicemen forwarded by the military authorities to the reporting civilian agency.

4. Civilian venereal disease control officers should actively participate in the work of the armed forces disciplinary control boards to safeguard the health, welfare, and morals of armed forces personnel.

Joint Program

These, in brief, are the general duties and responsibilities of both military and civilian authorities in their joint program for venereal disease control. Failure of one of the contracting parties to live up to his end of the agreement forecasts a pessimistic future for the military control program. However, there are times when, because of the exigencies of the moment, some of the services cannot be adequately carried out. Such a situation arose in Massachusetts. The demands of the United Nations in Korea, requiring the transfer of trained and key personnel to the front, left Fort Devens without trained venereal disease interviewers. As the rotation of men continued, this lack was sorely felt. Like many military stations in the United States, the venereal disease rate at Fort Devens did not require the full-time services of a venereal disease interviewer. However, there was no question that the military venereal disease control program would profit from the services of such an individual. Therefore, the services of three well-trained nurse venereal disease epidemiologists from the Massachusetts Department of Public Health were offered and accepted. These nurses carry out a specialized program in venereal disease control and operate from venereal disease clinics located approximately 10 miles from the post. From these clinics, the epidemiologists carry out their venereal disease control activities in a given number of communities surrounding their clinics. This pattern exists throughout the State, where there are 24 clinics located in general hospitals (with 3 exceptions), each with an epidemiologist, so that complete coverage of all communities in the State is assured.

The experiences of the Fort Devens hospital since September 1951, when the services of the epidemiologists were made available, to February 1, 1952, a period of 5 months, are summarized in this paper. The station hospital still has the services of these nurses and more complete reports will be given as data are accumulated.

Methods

A simple but effective system of contact investigation has been set up. The out-patient department facilities of the station hospital at Fort Devens have been so arranged that patients referred to the venereal disease clinics or voluntarily reporting for examination are seen in the morning. After an appropriate examination, the necessary laboratory tests are performed. Reports of the laboratory examinations are ready by 1:00 p. m., in time for the afternoon clinic. Patients who were examined in the morning are requested to return in the afternoon, when, with all laboratory reports available, a definitive diagnosis can be made. Once the diagnosis has been established and confirmed by laboratory tests, the patient is interviewed by the nurse epidemiologist in a private room at the clinic. The schedule for the nurses has been so arranged that, each afternoon 5 days a week, one epidemiologist is detailed for interviewing at the clinic. Two of the nurses report two afternoons a week, and a third at one afternoon session. If no patients are examined in the morning, the nurse on call for that afternoon is notified by phone, thus releasing her for other duties.

Function of the Epidemiologists

The epidemiologists have a threefold function. Their primary responsibility is to ascertain the identity and description of contacts, as well as circumstances surrounding the exposures, for example, place and date of encounter and exposure, and relationship of the contacts to the patient. This information is given to a corpsman, who transcribes it on the military epidemiological report forms (PHS-1421 VD) and routes copies of the form to the health departments of the States where the contacts are reportedly located, or to city health

departments when so indicated by military regulations.

The second responsibility of the epidemiologists, carried out during the interview, is to re-educate and reorient the patient.

Equally important is the third undertaking of the nurse, the proper indoctrination and individual training of the hospital corpsmen.

The names and addresses of all contacts are obtained whenever possible, regardless of whether they may be in Massachusetts or from other States or countries. The service is comprehensive. However, for contacts most likely to be found in Massachusetts, the nurse epidemiologists transcribe the contact data on Massachusetts forms in addition to the military reports. Copies of the Massachusetts epidemiological forms are sent directly to the epidemiologist in whose district the contact may be located, and the original copy, as well as the military forms, are sent directly to the Massachusetts Department of Public Health, division of venereal diseases. When complete identifying information is obtained, the data is immediately telephoned to the central office where it is the responsibility of the division staff to locate the appropriate nurse in the field and relay the information to her. The forms follow in routine fashion.

Such is the system which has been arranged—simple yet effective.

Results

During the period of January to August 1951, inclusive, a total of 175 cases of venereal disease was diagnosed at the United States Army Hospital, Fort Devens, Mass. There were 159 patients with gonorrhea and 16 infected with syphilis. Of the latter, 12 were in the primary or secondary stages (lesion syphilis) and 4 in the early latent stage. The corpsmen were able to elicit the names of 1.13 contacts per patient with gonorrhea and of 1.58 contacts per patient with lesion syphilis (table 1).

However, during the first 5 months of this study, September 1951 through January 1952, when infected patients were interviewed by the nurse epidemiologists from the Massachusetts Department of Public Health, division of venereal diseases, a total of 136 cases of venereal

disease was diagnosed at Fort Devens. Of this number, 113 represented cases of gonorrhea, 21 syphilis, and 2 granuloma inguinale. Of the syphilis patients, 13 were in the primary or secondary stages, 6 had latent syphilis, and 2 were in the late stages. The nurses were able to obtain 1.29 contacts per patient with gonorrhea; the contact-patient index for lesion syphilis was 3.46 (table 1).

Table 1. Results of contact investigation at Fort Devens, Mass.

Number of cases	Gonorrhea		Primary and secondary syphilis	
	Hospital corpsmen	Nurses	Hospital corpsmen	Nurses
Number of patients examined.....	159	113	12	13
Number of contacts named.....	179	146	19	45
With complete information.....	66	74	4	25

Brought-to-treatment index.....	1.31	2.44	.08	.38

¹ Includes 15 treated on suspicion.

² Includes 26 treated on suspicion.

Military Interviewers

Gonorrhea. The military interviewers were able to elicit identifying information on 179 contacts of the 159 patients with gonorrhea (table 1). The contact data were examined and it was concluded that complete identifying information had been obtained on 66 (36.9 percent). The information, whether complete or incomplete, was transcribed on the military epidemiological report forms and sent to the States in which the contacts were most likely to be found. As a result of the information furnished to the States, including Massachusetts, 61 (34.1 percent) of the contacts were found and examined. The epidemiological index was 0.33 since 53 of the contacts were found

to be infected. When the contact information was adequate, 56.1 percent of the contacts were located and examined in contrast to the 21.2 percent who were located when the contact data were incomplete.

Lesion Syphilis. There were 12 patients with primary or secondary syphilis and the military interviewers were able to obtain information on 19 of their contacts, a contact-patient ratio of 1.58 (table 1). The contact data were deemed complete or adequate in 4 (21.1 percent) and incomplete in 15 (78.9 percent) cases. The contact information was sent to the respective States and 10 (52.6 percent) of the contacts were found and examined, 5 in Massachusetts and 5 in other States. The epidemiological index was 0.17. When contact information was complete 75.0 percent of the contacts were located and examined in contrast to the 46.7 percent who were found when the information was incomplete.

Specialized Nurse Interviewers

Gonorrhea. During the period covered by this report the nurses interviewed 113 patients with gonorrhea and obtained information on 146 contacts, a contact-patient index of 1.29 (table 1). This is not very different from the 1.13 contact-patient ratio obtained by the military interviewers, and the difference between the two is not statistically significant. However, when the adequacy of the contact data and the number of contacts found and examined are studied, one finds a significant difference, for 50.7 percent of the contact information obtained by the nurses was complete and 43.2 percent of the contacts were found and examined. The epidemiological index for all States for gonorrhea was 0.47.

Lesion Syphilis. There were 13 patients with primary or secondary syphilis and the nurses obtained the names of 45 contacts, a contact-patient ratio of 3.46 (table 1). This is in contrast to a contact-patient index of 1.58 obtained by the military interviewers. The contact data were considered complete in 25 (55.6 percent) cases and incomplete in 20 (44.4 percent). These data were sent to the various States in the routine manner and 19 (42.2 percent) were located and examined. The epidemiological index was 0.38.

Table 2. Venereal disease contacts of military personnel at Fort Devens, Mass., investigated by the State of Massachusetts and by other States

Conclusions

Contact interviewing is a highly specialized art requiring the services of well-trained personnel. Experiences of the Massachusetts State Health Department with the Fort Devens hospital have been very satisfactory. They suggest that other Army hospitals might well consider the advisability of a closer liaison with civilian health authorities, particularly if well-trained military interviewers are not available. More careful attention to contact investigation is needed.

Summary

This paper summarizes the basic principles of a military venereal disease control program. It emphasizes that adequate control measures must have complementary action on the part of civilian authorities. It further describes the unique experiences of a State health department in not only interviewing military patients

for contacts but also engaging in the training of military hospital corpsmen in the highly specialized art of contact interviewing.

The study points up the need for highly trained personnel in carrying out contact interviewing, by comparing the results of interviewing by relatively untrained versus trained people. The hospital corpsmen who have had little training in interviewing were able to obtain 1.13 contacts per patient with gonorrhea and 1.58 contacts for lesion syphilis. In contrast, the nurses obtained 1.29 contacts for gonorrhea and 3.46 contacts for syphilis. With the information supplied by the military interviewers, civilian health departments were able to locate 34.1 percent of the gonorrheal contacts and 52.6 percent of the syphilis contacts. On the other hand, information supplied by the nurses resulted in 43.2 percent of the gonorrheal contacts and 42.2 percent of the syphilis contacts being found in spite of the fact that no disposition has been reported on 24.7 percent of the gonorrheal contacts and 17.8 percent of

the syphilis contacts as compared with 14.5 percent of gonorrheal contacts with no disposition from military interviewers and 10.5 percent for syphilis contacts.

Of striking importance was the epidemiological index. From information supplied by the hospital corpsmen, the epidemiological index was 0.33 for gonorrhea and 0.17 for syphilis. In contrast, the epidemiological indexes from information supplied by the nurses were 0.47 for gonorrhea and 0.38 for syphilis.

One of the important points brought out in this study is the obvious necessity for the States to improve their contact investigational activities (table 2).

Public Health Training Courses

In the spring of 1953, refresher training courses in the principles and practices of laboratory diagnostic methods and field training courses in insect and rodent control will be offered by the Communicable Disease Center, Public Health Service.

Laboratory subjects will include general bacteriology, enteric bacteriology, tuberculosis, virus diseases, rabies, parasitology, medical mycology, veterinary mycology, and microbiology for public health nurses. Instruction covers lectures, laboratory exercises, demonstrations, audio-visual aids, and group discus-

sions. Laboratory training courses will be offered throughout 1953.

Laboratory personnel of State and local health departments, Federal agencies, and nonprofit institutions are eligible for the laboratory series. Applications should be submitted through the appropriate State health officer or, for Federal personnel, through the bureau or division chief, and forwarded to: Medical Officer in Charge, Communicable Disease Center, Public Health Service, Box 185, Chamblee, Ga., Attention: Laboratory Training Services. Requests for application forms and a bulletin

describing the 1953 training series should be sent to the same address.

Personnel in State and local health departments and the Public Health Service are eligible for the courses in insect and rodent control. Persons from other organizations will be accepted if facilities permit. Applications should be made through the sponsoring agency to: Medical Officer in Charge, Communicable Disease Center, Public Health Service, 50 Seventh Street NE, Atlanta 5, Ga., Attention: Chief, Training Branch.

Both series of courses are scheduled as follows:

Insect and Rodent Control

March 23-April 3: Rodent control.
April 6-17: Insect control.

April 20-May 1: Rodent control.
May 4-15: Insect control.

Laboratory

March 16-27: Laboratory diagnosis of virus diseases.

March 16-27: Laboratory methods in medical mycology—cutaneous fungi (part 1).

March 16-27: Laboratory diagnosis of tuberculosis.

March 30-April 3: Laboratory diagnosis of tuberculosis (directors' course).

March 30-April 10: Laboratory methods in medical mycology—subcutaneous and systemic fungi (part 2). NOTE: Part 1, cutaneous fungi course, or equivalent education or experience, is a prerequisite.

April 6-10: Laboratory diagnosis of bacterial diseases (directors' course).

April 13-17: Laboratory diagnosis of parasitic diseases (directors' course).

April 13-17: Laboratory diagnosis of rabies.

May 4-8: Microbiology for public health nurses.

The Public Health Training Program Of New York State

By FRANKLYN B. AMOS, M.D., M.P.H.

ANY STATE health department training program naturally should be based on the needs, problems, and public health organizations existing in that State. For this reason, it is desirable to review briefly certain pertinent facts about New York.

New York State, covering an area of about 50,000 square miles, has a population, according to the 1950 census, of 14,830,192, with 7,891,957 in New York City. In addition, there are 11 other cities in the State with a population of over 50,000. There are 57 counties, exclusive of the 5 counties fully within New York City, and 929 towns, 549 villages, and 51 cities under 50,000 population. Town and city government is relatively stronger than either village government or county administration with the exception of the few counties in the State which have adopted an optional form of strong county government permitted by legislative action in the last several years. State government is well organized and many governmental services are performed by law by the State.

Local health services are provided through various administrative patterns. Each town, village, and city is required to have a health

officer and may employ other public health personnel. Under permissive legislation, any county may establish a county health department, and if it does so, all towns and villages within such county become a part of the county health district. Cities within the county may and usually are included also. Fourteen county health departments are established, serving populations varying from 24,000 to nearly 1,000,000. Ten cities with a population of over 50,000 and located in counties without county health departments have full-time, well-staffed health departments. The remainder of the State receives its public health services from the employees of the towns, the villages, and the counties, supervised and supplemented by the staffs of the State district health offices, which may, in many respects, be considered as multicounty health departments.

According to a recent tabulation, there are 3,548 positions budgeted for public health professional workers in major categories, exclusive of those in laboratories and hospitals (see table).

History of Program

Since 1913, the State public health council has had authority to establish qualifications for certain public health personnel employed by the State or its political subdivisions. In 1921, the State civil service commission was established, with authority to stipulate minimum qualifications for all State employees in classified positions. Similar provisions for

Dr. Amos, director of the office of professional training in the New York State Department of Health, discussed his State's public health training program at the training conference of Region III, Public Health Service, Federal Security Agency, Washington, D. C., on August 12, 1952.

minimum qualifications for employees of counties, cities, towns, and villages were added at a later date so that by 1945 at least minimum professional qualifications were required of all public health workers.

Full-time public health professional positions in New York State, July 1952

Professional category	Total	Employing health department		
		State	County and city ¹	New York City
Physicians.....	227	76	59	92
Nurses.....	2,269	129	943	1,197

¹ Only the cities over 50,000 included unless part of county health department; New York City not included.

In 1932, the public health council established certain minimum qualifications for public health personnel. These included graduate academic training or practical public health experience, or both, for all full-time health officers and all public health nurses. It was felt then that provision of an adequate number of public health physicians and public health nurses to satisfy the needs demanded by these regulations could be made only by developing a State training program. Plans for a program of health officer training were developed and put into operation in 1934. Expansion of the program has resulted in the training of public health nurses since 1936, of statisticians since 1938, of nutritionists since 1945, of health educators since 1948, and of sanitation personnel since 1951. Training has been received by more than 100 physicians, 600 public health nurses, 15 statisticians, 8 nutritionists, and 20 health educators.

Present Scope

The training provided at any given time depends upon analysis and evaluation of the needs.

This is done annually prior to the submission of the training budget. Some training activities have been discontinued and others decreased or increased as the needs varied.

In general, all training may be grouped in two categories:

Preservice training which may be required for the person to be eligible for appointment to the beginning permanent position.

In-service training needed for the permanent appointee to remain qualified for the position or to become eligible for a more responsible or more specialized position.

The need for preservice training is determined by position vacancies, both present and expected, by the qualifications established for the position, and by the supply of qualified applicants for the position and of the available applicants for training. Determination of the need for in-service training requires an analysis of the public health programs, both as to content and knowledge available, and the education, aptitude, and ability of the permanent workers.

The current training program includes 38 separate and distinct training activities, not including the orientation program for all new public health workers, nor the clinical training conducted as a routine function in the hospitals, nor the on-the-job training constantly in effect through staff meetings, conferences, or short courses provided wholly within the department.

Fourteen training programs are for physicians. One provides a year's supervised experience and residency training approved by the American Board of Preventive Medicine. Another permits physicians to be sent, on stipend, to an approved school of public health for one academic year. Tuberculosis public health physicians are trained in a 14-month program which includes 6 months' clinical training in a tuberculosis hospital, 2 months' general experience in public health, and 6 months' specialized experience in tuberculosis control. Physicians may be trained for maternal and child health positions for a year at a school of public health supplemented by 6 months' planned experience in a local health department. One year of clinical training in tuberculosis is given to physicians to qualify them for beginning clinical positions in the State health department.

ment. Specialized training in rheumatic fever includes 1 year of clinical experience supplemented by a year in a school of public health. Training for physicians in laboratory work consists of 1 year of practical experience under close supervision which, when added to the qualifications the physician must have to enter such training, permits him to meet the requirements for director of a local laboratory. Clinical training in cancer, heart disease, or cerebral palsy can be given to physicians not employed by an official health agency but who will subsequently be contributing to official health programs. Short, formal courses in public health administration varying from 3 days to 2 weeks are provided for public health physicians. Short courses in clinical subjects such as poliomyelitis, tuberculosis, cancer, or heart disease are also arranged for this group.

The department aids in providing postgraduate medical education for the 30,000 private practitioners in the State in several ways. In a cooperative program with the State medical society, honorariums are paid to lecturers at local medical meetings and special short courses are arranged on the subjects of rheumatic fever and rheumatic heart disease, cardiovascular diseases, pediatrics, and obstetrics. In a joint program with the University of Buffalo School of Medicine, comprehensive postgraduate medical education is provided.

The provision of practical public health experience for a limited number of medical students is another important activity. Known as the junior public health intern program, it accepts 30 of the State's 900 medical students for 1 to 4 months' training. The students work under the immediate supervision of a well-qualified public health physician in the State health department or in a selected local health department. Their public health training is comparable to the clinical training at hospitals they receive while in medical school.

The single training program for dentists consists of a 2 weeks' course in children's dentistry for practicing dentists in the State.

Twelve of the training programs are for nurses. One consists of 6 months' supervised field experience with a general public health nurse. Another is an academic year in public health nursing, which leads to qualification as

public health nurse for field service. Further academic training of 1 year is provided for nurses who will be responsible for supervising or directing other public health nurses. Training in the care of premature infants and the newborn, in pediatrics, in cancer, in tuberculosis, or in physical therapy is given to public health nurses or nurses employed by other health agencies and by hospitals.

Short courses for nurses, consisting of 4 weeks or less of academic or clinical instruction, observation, and training, are also provided in several specialized subjects. Nurses may be sent for a 3 weeks' course in contact investigation in venereal disease. Two months' experience in public health is provided for student nurses from the schools of nursing whose graduates are then qualified as public health nurses for field service.

One program for nutritionists provides a 12-month apprenticeship under the guidance and supervision of a public health nutritionist.

There are three programs for public health educators. One provides supervised field experience for 1 year, and another provides for sending these trainees to schools of public health. Short courses in health education techniques are made available for health educators in the State. One training program for statisticians sends them to a school of public health for an academic year. Six programs are for groups of sanitation personnel. One program for public health engineers and sanitarians consists of short courses of 1 to 2 weeks' duration in such subjects as epidemiology, public health administration, and public health education.

A 1 to 2 weeks' course is conducted to qualify water and sewage treatment plant operators. A 2 weeks' course is offered at least once each year for dairy and milk inspectors. A 12 weeks' course for sanitary inspectors is given jointly by the State health department and the Public Health Service in a field training center at Yonkers. Other shorter courses for sanitary inspectors are also given at this school. Short courses lasting from 1 day to 1 week are given for employees and operators of camps, restaurants, swimming pools, and similar facilities. There is no provision at present for full-year academic training in the school of public health for public health engineers and sani-

tarians, but this is the next step planned for the development of the sanitation training program, which has been in operation for only 1 year.

Three training programs are for technicians. One consists of a year's training in photo-fluorography. Two others of short duration are for laboratory technicians.

This listing of public health training given shows the present scope of the program. It is not exactly the same as it was in 1951 nor as it will be in 1953, but it shows the variety of content included and method of providing training.

Administrative Organization

Training is a vital part of public health administration. As such, it must be carried out by many people in administrative positions, including those in the local health departments as well as those in the State health department. Various schools, of course, also have an important part in providing adequate training for public health workers.

The administrative organization of training within the State health department is the result of evolution over the 18 years it has performed this function. Naturally, the training for any specific group of personnel can be done best by those providing service in that category; therefore, as new training programs were added, units were established within the appropriate division, bureau, or office to conduct the training of the members of that unit. As the training function of the department began to assume major proportions, it became evident that an office to integrate and correlate the training activities was needed. In 1948, the office of professional training was established as a part of the executive division and was delegated this responsibility. There was continued recognition of the need for providing training within the service units, however, and one or more professional workers in many of these units are today devoting full or part time to the administration of the training programs outlined.

The immediate staff of the office of professional training consists only of the director of the office and necessary stenographic assistance. Three nurses give full time to a training unit in the bureau of public health nursing and one

sanitary engineer devotes full time to a training unit in the bureau of environmental sanitation. In addition, one person in the office of health education, one in the division of medical services, one in the bureau of nutrition, one in the office of vital statistics, one in the division of laboratories and research, and two in the division of tuberculosis control devote part time to training activities.

Unification of training functions, including the common utilization of training facilities, determination of uniform policies and procedures, and equitable distribution of funds, is accomplished by frequent conferences among the members of the department who have a primary responsibility for professional training activities and by a regularly scheduled monthly meeting of all these persons. Reports to the commissioner of health on training policies and procedures and the training budget are submitted through the office of professional training. These reports and the budget represent the combined thoughts, interests, and needs of all persons concerned with training.

Budget Provisions

Adequate budgetary provisions are essential for the conduct of public health training programs. This year, the State health department has a training budget of \$624,495. Of this amount, \$252,000 is a State appropriation and the remainder is allocated from Federal funds. Salaries of a few of the people devoting full time to training are included in this budget, and the remainder is for the payment of stipends, travel expenses, and tuition for trainees. Other items of training expense not included in the training budget are the salaries and expenses of the many persons doing training on a part-time basis, the production of materials, and incidental items of expense incurred in connection with training. These are absorbed in the regular budgets.

Stipends of trainees are determined according to a formula which is acceptable to both the health department and the budget director's office. This formula provides that persons in preservice field training be paid 75 percent of the beginning salary of the position for which

they are training, those in academic preservice training who have dependents, 65 percent of the beginning salary, and those who have no dependents, 50 percent; those in in-service academic training, 80 percent of their salary at the time they go on leave of absence if they have dependents and 60 percent of such salary if they do not have dependents.

Typical Training Program

A description of the health officer training program will show the general pattern of all programs.

Advisory Committee

Seven members compose the advisory committee for the health officer training program. The deputy commissioner, the assistant commissioner for local health services, and the director of the office of professional training serve ex officio. Other members are the dean of a medical school, a county health commissioner, the assistant State commissioner of education, and the executive director of a voluntary health agency. The latter was formerly director of a school of public health, and if this were not so there would be an additional member representing that field.

The committee has no executive function but advises on policy and procedural matters. It meets regularly to consider qualifications of applicants, length of training, content of training, educational methods employed, or specific problems arising from time to time. Although the committee has no authority of direction, the advice given is usually decisive in future action.

Trainee Qualifications

Trainees must be graduates of an approved medical school; must have interned 1 year in an approved hospital; must be United States citizens or give assurance that they will be citizens upon completion of their training; must be licensed to practice medicine in the State or have reasonable expectation of being licensed upon completion of training; and preferably should be not over 35. The citizenship and license requirements are necessary to qualify for permanent appointment. The age require-

ment is not absolute, but exception is made only under unusual circumstances. Experience has shown a more probable expectation of success both during and after training for those who enter the field of public health early in their professional careers.

Selection

Applicants with the qualifications outlined are interviewed by a committee composed of three members of the State health department. Agreement on the suitability of a candidate must be unanimous before he is accepted for training.

Content

The training consists of the two parts previously listed as separate training programs: a year's residency training, and an academic year at an approved school of public health. A part or all of the residency training must be completed prior to attending the school of public health if such attendance is on stipend from the State health department. Usually, the minimum period which must be completed is 6 months, a requirement serving a threefold purpose: It permits the physician to determine whether public health is the field he wishes to enter; it permits the State health department to evaluate the physician before committing itself to financing the academic training; and it gives the trainee a background for attending a school of public health.

Representatives of the schools have concurred that such training is necessary for physicians not otherwise possessing some public health experience if they are to receive the maximum benefit from their academic experience.

During the first 6 months of the residency program, the physician follows closely a guide for residency training, which outlines the experiences in all phases of public health practice that he will likely encounter when he accepts a position as health officer. During the second 6 months, the resident serves as an assistant to a county or city health commissioner or district health officer, performing designated duties under close supervision.

The residents are brought into the central office in small groups for three 1-week periods

tarians, but this is the next step planned for the development of the sanitation training program, which has been in operation for only 1 year.

Three training programs are for technicians. One consists of a year's training in photofluorography. Two others of short duration are for laboratory technicians.

This listing of public health training given shows the present scope of the program. It is not exactly the same as it was in 1951 nor as it will be in 1953, but it shows the variety of content included and method of providing training.

Administrative Organization

Training is a vital part of public health administration. As such, it must be carried out by many people in administrative positions, including those in the local health departments as well as those in the State health department. Various schools, of course, also have an important part in providing adequate training for public health workers.

The administrative organization of training within the State health department is the result of evolution over the 18 years it has performed this function. Naturally, the training for any specific group of personnel can be done best by those providing service in that category; therefore, as new training programs were added, units were established within the appropriate division, bureau, or office to conduct the training of the members of that unit. As the training function of the department began to assume major proportions, it became evident that an office to integrate and correlate the training activities was needed. In 1948, the office of professional training was established as a part of the executive division and was delegated this responsibility. There was continued recognition of the need for providing training within the service units, however, and one or more professional workers in many of these units are today devoting full or part time to the administration of the training programs outlined.

The immediate staff of the office of professional training consists only of the director of the office and necessary stenographic assistance. Three nurses give full time to a training unit in the bureau of public health nursing and one

sanitary engineer devotes full time to a training unit in the bureau of environmental sanitation. In addition, one person in the office of health education, one in the division of medical services, one in the bureau of nutrition, one in the office of vital statistics, one in the division of laboratories and research, and two in the division of tuberculosis control devote part time to training activities.

Unification of training functions, including the common utilization of training facilities, determination of uniform policies and procedures, and equitable distribution of funds, is accomplished by frequent conferences among the members of the department who have a primary responsibility for professional training activities and by a regularly scheduled monthly meeting of all these persons. Reports to the commissioner of health on training policies and procedures and the training budget are submitted through the office of professional training. These reports and the budget represent the combined thoughts, interests, and needs of all persons concerned with training.

Budget Provisions

Adequate budgetary provisions are essential for the conduct of public health training programs. This year, the State health department has a training budget of \$624,495. Of this amount, \$252,000 is a State appropriation and the remainder is allocated from Federal funds. Salaries of a few of the people devoting full time to training are included in this budget, and the remainder is for the payment of stipends, travel expenses, and tuition for trainees. These are absorbed in the regular budgets.

Stipends of trainees are determined according to a formula which is acceptable to both the health department and the budget director's office. This formula provides that persons in preservice field training be paid 75 percent of the beginning salary of the position for which

Tennessee Accident Fatalities, 1946-50

By ANNA LOVE SULLIVAN, B.S.

ACCIDENTS caused the deaths of 9,095 residents of Tennessee during the 5 years 1946-50, or an average of 1,819 deaths per year. In this same period, accidents were the fourth principal cause of death in Tennessee for persons of all ages.

When considered by age groups, however, accidents were found to be the leading cause of death for persons 1-24 years, the second principal cause of death for persons in the age group 25-44, and the fifth principal cause for all persons 45 years of age and over. (See fig. 1.)

Motor vehicle accidents outnumbered all other types of accidents in Tennessee for the 5-year period under study. The number and percentage of deaths by type of accident are shown:

Deaths From Accidents by Type
(1946-50)

Type	Deaths	Percentage
Motor vehicle.....	3,437	37.8
Home.....	3,072	33.8
Other public.....	1,821	20.0
Occupational.....	565	6.2
Other.....	200	2.2
Total.....	9,095	100.0

For Tennessee residents in the 1-24 age bracket, accidents caused more deaths over the 5-year period than did the other five leading causes of death combined. In this age group, accidental deaths numbered 2,739, while the total number of deaths was 2,687 for the next

five leading causes of death—tuberculosis (second), influenza and pneumonia (third), malignant neoplasms (fourth), diseases of the heart (fifth), and homicides (sixth).

During 1946-50, 1,547 children under 15 died from all types of accidents, an average of 309 deaths for each of the 5 years.

The death rates according to type of accident resulting in death varied according to age. In young adults, the motor vehicle accident rate was very high, followed by a slightly lower rate for the age group 30-54 years. But these lower rates were followed by higher rates for persons 55 and over. For the age groups between 15-64 years, death rates from motor vehicle accidents were higher than were the rates for other types of accidents.

Home accidents caused many deaths in children below 10 years and resulted in a very high rate in old age. Occupational accidents caused approximately six deaths per 100,000 population per year for those 25 years of age and over.

Motor Vehicle Accidents

During 1946-50, on the average, 687 deaths per year from motor vehicle accidents were recorded. The trend of death rates since 1914 shows that deaths caused by motor vehicle accidents increased steadily until 1936, from the 1914 rate of 1.6 deaths per 100,000 population, to 27.9 in 1936. The high rate of 1936 was followed by lower rates, which are attributed to the restricted use of cars during World War II. Accident death rates since 1946 have again had a steady increase, reaching the rate of 25.9 in 1951.

Miss Sullivan is a statistician in the statistical service of the Tennessee Department of Public Health.

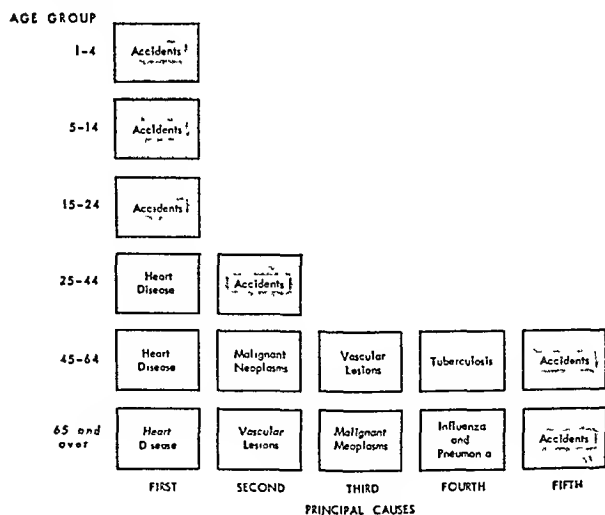

Collisions with other motor vehicles caused many accidents. Deaths from this type of accident numbered 965 or 28.1 percent of all motor vehicle accidents. Collisions with pedestrians caused 939 deaths (27.3 percent). Noncollision accidents killed 906 persons (26.4 percent), and other and unspecified motor vehicle accidents numbered 627 (18.2 percent).

The death rate for drivers was very high in the 10-34 age group, with the highest rate in the 15-24 group, indicating the need for accident prevention education in high schools. Accident death rates were very high for male drivers, higher than the rates for female drivers in all age groups.

The passenger death rate was also very high in the 15-24 age group. For pedestrians, the death rates were high in the older age groups with very high rates for males 65 and over.

The average annual death rates per 100,000 population by age and sex reveal a higher death rate for males in all age groups, with the highest rate (58.0) in the 15-24 age group. The next highest rate is that of males 65 and over. For females, the highest rate (14.3) occurs in the same age group, followed by the rate of 12.1 for the 55-64 group. Females 15-24 years of age had a rate of 11.6.

Figure 1. Relationship of accidents as principal cause of death to other causes, by age, Tennessee, 1946-50.

On the week end, the daily occurrence of accidents was higher than at any other time. The week-end increase started on Friday with 439 deaths (13.7 percent) occurring. The number

Useful Application of Data

That an aggressive program of accident prevention would help to save some lives is apparent from any study of routine accident data. Through dramatic use of accident statistics, the health department can inform members of its community about the needless tragedies caused by lack of caution in the home and on the highway.

Tennessee is doing just this. The accompanying paper is one illustration of how accident statistics can be usefully applied. Another illustration is the release in 1952 of a 20-page pamphlet "Stop Look Listen—Prevent Accidents" by the Tennessee Department of Public Health. The fatality statistics presented in this issue are a slight abridgment of the information contained in the pamphlet and reported in March 1952 to the Tennessee Public Health Association.

was greatest on Saturday (23.2 percent) and decreased to 18.0 percent on Sunday. Fewer accidents occurred on Tuesday, Wednesday, and Thursday, with a low of 10.4 percent on Thursday.

Average annual death rates per 100,000 population from motor vehicle accidents were also studied by counties for 1946-50. Very high rates were noted for 35 of the 95 counties in Tennessee. Davidson County, in which Nashville is located, had the highest rate (24.0) of four Tennessee counties (Davidson, Hamilton, Knox, and Shelby), containing the four largest cities. Shelby had the lowest rate, 15.9.

Home Accidents

Although persons of all ages are exposed to hazards in the home, the highest death rates from home accidents were found in the two age groups, under 5 years, and 65 and over. Falls were the most frequent cause of home accident deaths. Of the 1,332 deaths (43.4 percent) from falls, 1,124 (84.4 percent) of all falls occurred in the age group of 65 and over. Con-

Figure 2. Fatal home accidents by type and age group for 5 years, Tennessee, 1946-50.

flagrations, burns, and explosions came next with 818 deaths.

Accidental deaths from firearms were noted for all ages. Twelve deaths were those of children under 5; 53 deaths were in the age group of 5-14. For adults 15-64 years of age, 154 deaths were recorded.

Of the 818 deaths from conflagrations, burns, or explosions in the home, 439 were the result of fatal burns and explosions other than in a burning building. Many deaths (79) were caused by burns from open grates; half of these (39) were of persons in the age group 65 and over; and 14 were of children 0-4 years. Explosions caused 69 of the 439 deaths with the largest number occurring in the 25-44 age group. Scalds killed 53 with 19 deaths occurring in the age group 65 years and over. Burned fatally by stoves were 25 children under 5 years. The age group 65 and over had more deaths (140) of the total 439 than did any other age group. A total of 101 deaths, the next highest number, occurred to children 0-4 years.

For children under 15, over half of the 1,547

deaths from all types of accidents (866 or 56 percent) were from accidents in the home. There were 647 deaths of children under 5. Conflagrations and burns accounted for 233 deaths—asphyxiation and suffocation for 244.

Other Public Accidents

Many fatal accidents occur every year in public places. In Tennessee, there were 1,821 such deaths in the 5 years studied from other than motor vehicle accidents. They have been tabulated by transportation and nontransportation, and by type of accident.

Of the 608 deaths caused by transportation other than motor vehicles, 248 were from railroad accidents where no motor vehicles were involved, 181 were due to water transportation accidents, and 146 to air transportation.

Drownings occurred more frequently in June and July than in other months and caused 620 deaths in the 5-year period.

Occupational Accidents

Industrial or occupational accidents are defined as accidents arising out of or occurring in the course of gainful employment exclusive of injuries to domestic servants and to persons involved in public transportation accidents. Tennessee had 565 occupational accident deaths in the period studied.

Leading in occupational accidents were agricultural accidents. Of the total 565 fatalities, there were 152 accidental deaths in agriculture, an average of 30 per year. Ninety-seven deaths (a yearly average of 19) occurred in employment in transportation and public utilities; and 90 deaths (an average of 18 per year) in mining and quarrying industries. Manufacturing industries had the lowest number, 71—a yearly average of 14.

Reactivity of VDRL Antigen Suspensions Made at Various Temperatures

By PAUL FUGAZZOTTO, Ph.D.

WHenever a study is conducted to evaluate the performance of serologic tests for syphilis, the final analysis usually reveals a considerable "spread" in the levels of sensitivity and specificity attained by the participating laboratories, irrespective of the test procedure or the kind of antigen employed. As a matter of fact, wide differences in results are obtained even when all participants use the identical test material in the same test procedure. For example, in a recent National Serologic Laboratory Evaluation all interested participants were given the same VDRL test material to use in the studies. When the results were tabulated it was evident that the reactivity levels shown for the VDRL test varied to essentially the same degree as those shown for other test procedures in which few if any of the participants used the same test material. It appears, therefore, that the reproducibility of serologic test performance is dependent upon the standardization of other factors (besides the antigen) which have not been well enough defined in the literature, and which are therefore poorly or insufficiently controlled in practice. Experience has shown that environmental temperature ("room temperature" so called) is one such factor.

The present work was undertaken to obtain data on the effect of variations in environmental

temperature on the physical appearance and reactive nature of a flocculation test antigen suspension.

Method

The VDRL test was used for this study. In order to avoid features involving differences of opinion, it seemed well to keep the study as objective and tangible as possible. To avoid further complications in interpretation of results, the study was limited to temperature variations introduced only at the point in the procedure where the saline-antigen suspensions are prepared. To simulate conditions comparable to variations in room temperature, all the materials required for preparation of the suspensions (except the antigen) were placed in the refrigerator or in the incubator for periods of time sufficient to impart different temperature levels to them. (The bottle of VDRL antigen was left in the environment of the laboratory: 22.4° C.) Using these various materials and following the stipulations set forth in the serologic test manual (1), 10 saline-antigen mixtures were made. Immediately after each suspension was made, a thermometer was placed in the solution to determine the temperature of the resulting antigen suspension. These values were recorded, and for sake of convenience were designated as "suspension temperatures." Then the suspensions were allowed to establish equilibrium with the temperature of the laboratory (22.4° C.) before they were used in the comparative tests. From this point on, meticulous care was taken to as-

Dr. Fugazzotto is the chief serologist in the bureau of laboratories, Indiana State Board of Health, Indianapolis.

Table 1. Comparative sensitivity of VDRL antigen suspensions prepared at various "room temperatures"

[Tests with pooled reactive serum in series dilution]

Antigen No.	1	2	3	4	5	6	7	8	9	10
Suspension temperature, ° C.	15.3	18.2	19.4	21.2	21.8	22.7	23.6	24.8	29.6	37.0

1:4	2	3	3'	4	3'	3	3	3	2'	1'
1:8	1	1'	2	2	2	2	1'	1'	1	±
1:16	±	1	1	1	1	1	1	±	±	—
1:32	—	±	±	±	—	—	—	—	—	—
1:64	—	—	—	—	—	—	—	—	—	—
Total pluses	3.5	6.0	7.0	7.5	6.5	6.0	5.5	5.0	4.0	2.0

Note: The mark (') denotes a reaction slightly stronger than the plus reading shown.

sure identical treatment of the reagents. The serologic test results were read by a well-trained technician who had no previous knowledge regarding the nature and purpose of this study. The recordings were made in terms of pluses for convenience of comparison.

Results

The suspension temperatures, as observed and recorded immediately after preparation of the suspensions, ranged from 15.3° to 37° C. (table 1).

The first step in studying these preparations consisted in an examination of the suspensions themselves. To several chambers of a Kline test slide there was delivered 0.05 ml. of VDRL buffered saline. One drop of each antigen suspension was dispensed into a separate chamber of this slide, the slide was tapped gently to disperse the particles, and the material was examined under the microscope. The slide was then placed on a conventional agitating machine at 180 rotations per minute for 4 minutes, and the material examined again.

In this series of suspensions there was a wide range in particle size: very fine pinpoint at the low temperature extreme to very large needle-like particles at the high temperature extreme. With the exception of suspension No. 10 (in which the very large particles had a tendency to become entangled on agitation) there was no appreciable change in the appearance of the

material on the slide after the 4-minute agitation.

The next step in the study of these suspensions was to test their sensitivity to reactive serum. For this purpose, a mixture of reactive serums was prepared; a series of saline dilutions was made by the double dilution method, and these dilutions were tested simultaneously in the usual manner with all 10 antigens. In table 1 are given the results obtained with each antigen on each dilution of serum.

Glancing over these results, we can see a definite reactivity curve having a peak in sensitivity at the level of antigen No. 3 or 4. The totals of the pluses shown at the bottom of the table are not necessarily significant in themselves, but are given as a means of expressing the sensitivity curve. As indicated here, the sensitivity was greatest for the antigen prepared to have a temperature of 21.2° C.

Finally, comparative tests were done on a group of 36 routine clinical specimens. These specimens were selected because they were weakly reactive in the Mazzini test. For this work, only 5 of the 10 suspensions were used.

On analyzing the results obtained with this group of 36 specimens it was found that the data could be divided into two subgroups because of the two reaction curves represented (see chart): subgroup A, in which the paraboloid type of reaction was displayed, and subgroup B, in which the reaction seemed to be the semiparaboloid type. In order to show the uniform pat-

tern of reactivity displayed by this series of antigen suspensions when used on individual test serums, the entire protocol, separated accordingly, is given in table 2. The totals and averages of the pluses are also given as an expression of the over-all picture.

The reaction curves are better illustrated by the chart, in which the average plus readings (shown for both subgroups in table 2) are plotted against the respective "suspension temperatures."

The fact that the curves in the chart show a difference in elevation can only be considered a coincidence. On the other hand, the difference in the scope of the curves seems to be due to the nature of the serums under test. Irrespective of the type of reactive specimens involved, however, there was an obvious decrease in sensitivity of the suspensions as the "suspension temperatures" became elevated (above 22° or 23° C.). In addition to this, the suspensions prepared at the higher temperatures were rather coarse and more difficult to evaluate. Suspensions such as No. 10 would definitely be considered unsatisfactory, even by the inexperienced technician.

Discussion

In considering the effect of temperature on serologic tests we must not fail to recall the work of Kahn, who has long shown with one form of "verification test" that, irrespective of its diagnostic value, differences in reactions are very often obtained under different environmental temperatures. All syphilis test antigens in present use are derived from essentially the same material and, whether we realize it or not, as long as one serologic test procedure is affected by environmental temperature, any procedure we may choose to employ is bound to be similarly affected. The only difference between the above-mentioned verification test and routine serology is that in the former each serum is tested in triplicate and the effects of various temperatures on the colloidal-chemical reaction can be seen side by side. In routine serology a given procedure is applied under only one undetermined and uncontrolled set of environmental temperatures and conditions. No comparative effects are seen; and there is no assur-

Variation in the sensitivity of VDRL antigen suspensions and temperature at which the saline-antigen mixtures were made.

ance that the test results would be duplicated on another day, or in another laboratory.

The philosophy advanced here is that "room temperature" is not a standard, designated by any particular line on a thermometer. The term itself serves only as a means of making the distinction between the main bulk of the laboratory space and the controlled thermal equipment, such as the refrigerator, incubator, and autoclave. It designates a place more than it does a condition. The thermometer reading in that place can vary over wide limits, and the fact that we ignore this in our routine work does not prevent it from exerting its influence on the test. Normal room temperature may range anywhere from near 0° C. to above 37° C. depending on the season of the year, geographic location of the laboratory, position of the room in relation to the rest of the building and the points of the compass, presence or absence of large electrical and steam equipment, air conditioning, windows, and many other features. Furthermore, it may vary on any one day from place to place in the room and from time to time. Reagents kept in such a laboratory must be expected to have the temperature of their immediate environment: cooler near the floor, warmer higher up. In winter they will be cooler in a cabinet on an outside wall, warmer in a cabinet on an inside wall—vice versa perhaps in the summer.

A good example of the type of situation that

actually obtains in laboratories is illustrated by an experience in a rather large, air-conditioned private laboratory which had a room temperature of 23° C. (75° F.) on a day when the out-of-doors temperature was -10° C. (14° F). The temperature in the cabinet hanging against an outside wall and containing the glassware, saline, and antigen was 8° C. (46° F). While the materials were used in the room at 23° C., the temperature of the reagents did not at all approach that of the room when the antigen suspension was made, not to mention the fact that the antigen itself had in reality been refrigerated for at least one period of approximately 12 hours prior to its use. Yet the technician considered his work satisfactory; he had complied with the instructions in the literature and had been using the material at room temperature.

The data given in this report are not presented to specify the suspension temperature at which the VDRL test antigen suspension should be made; for in the first place, the optimum suspension temperature might well differ for each alcohol preparation of the material (a phase which has not yet been studied); and second, the incorporation of such a stipulation in the test procedure is a matter for the consideration of the test authors. This report is intended only to record the observation that differences in the appearance of the microscope field as well as differences in sensitivity could be demonstrated to result from controlled variations in room temperature even though the variations were affected for only one of the many phases in test procedures where temperature can and does vary in actual practice.

The resulting differences in sensitivity of the antigens studied may not appear especially startling; and perhaps for practical purposes such variations can be considered negligible. However, if we carefully study serologic test procedures from the standpoint of the numerous combinations of conditions under which differences in temperature and other factors can easily be introduced, without violating the instructions given in manuals of procedures, we can readily understand that to a great extent inconsistencies in results are without doubt due to the "negligible" effect of one variable superimposed upon that of others.

The effects of all the negligible features are just as important to that serologic summation which we call the serologic test report, as seconds are to the accumulation of time.

Conclusions

Since temperature influences the colloidal make-up and behavior of syphilis test antigen suspensions, and since the temperature can be controlled for certain phases of serologic test procedures, the optimum temperature range for these phases should be determined and speci-

fied in the literature. The term "room temperature" has little or no meaning from a scientific standpoint, and should be deleted from serologic test descriptions.

Summary

In a laboratory with a "room temperature" of 22.4° C. it was possible, under controlled conditions, to prepare antigen suspensions under conditions of temperature ranging from 15.3° C. to 37° C. With the use of these antigens (brought to a room temperature of 22.4° C.) data were obtained showing that the microscopic appearance and the sensitivity of a flocculation test antigen suspension (VDRL) are in a degree determined by its temperature at the time it was made.

This report is offered as an indication that environmental temperature is one of the factors contributing to wide variations in serologic test performance.

Dr. Foard Retires

Dr. Fred T. Foard, chief of the branch of health, Bureau of Indian Affairs of the Department of the Interior, retired as an officer of the Public Health Service on October 31, 1952, after 36 years of service. He is now director of the division of epidemiology for the North Carolina State Department of Health.

Dr. Foard began his public health career by assisting in control of malaria, typhoid, and other environmental diseases in the West and Southwest. In 1920 in Montana he organized the first full-time county health unit in the Rocky Mountain tier of States, and assisted health officers in 10 other western States to organize district and local units when funds became available under the Social Security Act.

Recent Progress in Cancer Research

By JOHN R. HELLER, JR., M.D.

THE MANY recent advances in cancer research make possible the cure of more cancers today than 20 years ago. Unless the cancer is far advanced, modern surgery or radiation, or a combination of the two, now offers the patient a greater opportunity for survival. There is also a better outlook for patients with advanced cancer who may be beyond the hope of permanent cure. New palliative measures have been developed which may prolong lives in comfort and increase their usefulness. All of this is possible even though knowledge of the etiology of cancer is slight, and an all-purpose cure for cancer's many forms is lacking.

The fact that one can regard cancer in such an encouraging light is highly significant, for the concerted attack against it is relatively new. Modern cancer research goes back about 50 years, but only since the end of World War II have significant sums of money been available for this purpose. Support and coordination of research are now being provided on an unprecedented scale, and many of the ablest investigators in the Nation are teamed in an effort to conquer cancer.

Nonetheless, cancer poses a dilemma which few other diseases can match. It is a complex public health problem because in cancer we are dealing not with a single disease, but with many

diseases. The more data that are accumulated in the research laboratories, the more there appears to be learned about the cancerous process, its growth, and its control. The multitude of new approaches that have come to light seem to branch out into an almost infinite number of ideas. There appears to be an endless amount of knowledge which can be accumulated about cancer.

The vastness and diversity of cancer research can be illustrated by reviewing some of the many approaches employed by cancer investigators.

Basic Research

A large part of cancer research is devoted to basic studies which increase understanding of the carcinogenic process and tumor development. Advances in basic research come slowly and seldom make headlines, but they are vital to the search for better methods in diagnosis, control, and therapy. The advances noted here by no means cover the entire field of basic research, but rather illustrate the kind of original work being done in laboratories of this country.

Among the advances in the basic biological sciences are those which have emerged from tissue culture laboratories. An important contribution which will make possible more effective use of tissue culture in the study of both normal and cancer cells is the three-dimensional tissue culture technique developed by Earle and his associates at the Public Health Service's National Cancer Institute (1). These scientists have grown massive cultures of tissue cells in the interstices of three-dimensional masses made up of thousands of glass rings. Many

Dr. Heller since 1948 has been director of the National Cancer Institute in the National Institutes of Health of the Public Health Service. He presented the material upon which this paper is based as the William Chester Warren Memorial Lecture at the Emory University Postgraduate Clinic, June 6, 1952.

applications for this technique are foreseeable. Already it has been applied in collaborative studies with the Naval Medical Research Institute to obtain large cultures of human epithelial cells for skin grafting purposes.

A new technique for growing cancer cells outside the body in the form of recognizable tissues has been developed by Leighton of the National Cancer Institute (2). His sponge matrix method for tissue culture employs an ordinary cellulose sponge as the skeleton on which the cancer cells are grown. Cells grown in this way form organized aggregates which frequently resemble the tissue pattern present in the living animal. This method has been used to grow many animal tumors and at least two human tumors, a malignant melanoma and a chondrosarcoma. The melanoma grew very well and produced new pigment within the sponge. The sponge-grown tissue can be sectioned, stained, and studied with the same methods used in examining tissues from the body. This technique for tissue culture might be used to study the direct effects of drugs, hormones, or radiations on neoplastic tissues or to study the factors, and perhaps the patterns, involved in tumor growth and metastases.

A valuable tool for the study of carcinogenesis, tumor development, and related problems has been developed at Yale University by Greene, who has transplanted human tumors to the brains of mice and guinea pigs (3). With the exception of brain neoplasms, however, only tumors which had metastasized were transplantable. Human tumors were grown in mice for 70 to 90 days before the mice died. In guinea pigs the tumors grew for as long as 90 to 100 days.

A new medium for the growth of malignant tumor tissue which conceivably may be applied to problems of human cancer has been discovered by Lutz at Boston University (4). He has used the cheek pouch of the hamster as a site for the growth of neoplastic tissue, both homologous and heterologous, under conditions in which frequent observation and exact measurements can be carried on for long periods. Human tumors and tumors from the rat, mouse, guinea pig, and frog have been grown by this means.

Among the recent basic studies relating cancer to prolonged hormonal imbalance are those

of Morris and his associates at the National Cancer Institute. These investigators have recently developed transplantable cancers of the thyroid gland of mice following the ingestion of thiouracil, a goiter-producing drug which inhibits the secretion of thyroxin (5). These cancers, when growing in normal animals, provide valuable material for experimental research dealing with problems of thyroid cancer and hormonal imbalances, and aid in the search for improved methods of using radioactive iodine in the treatment of thyroid cancer in man.

Tools for the development of cancer therapeutic measures have been provided by the chemical-screening projects conducted at the Memorial Hospital for Cancer and Allied Diseases, the National Cancer Institute, and other laboratories. Shear and his associates at the National Cancer Institute have tested more than 3,000 chemicals for tumor-damaging ability (6). About 500 have been found to damage sarcoma, 37 in mice following a single injection of a near-lethal dose. It must be emphasized that these compounds are not yet clinically useful, but they provide a stockpile from which it may be possible to develop drugs to treat cancers of man. It is essential that chemicals with some potential ability to affect the growth of cancer be tested thoroughly on experimental animals before they are made available for clinical trial. Screening itself is only the beginning of a chemotherapy program; it must be followed by systematic and extensive pharmacological research.

Clinical Research

In addition to advances in basic research, cancer investigators have reported encouraging progress in the search for improved methods in treatment and diagnosis.

The treatment of cancer, once limited to the use of surgery and radiation, has been expanded to include anticancer drugs, hormones, and radioactive isotopes (7). Although the cure of cancer still remains with surgery and radiation, these new agents are valuable additions to the therapeutic program. Perhaps progress should not be measured entirely by cure, as Steiner of the University of Chicago has pointed out, for this criterion fails to give credit to palliation

The first step in the sponge matrix method for tissue culture, developed at the National Cancer Institute. With an ordinary razor blade, thin slices are cut from narrow strips of sponge; then the slices are washed, sterilized, and placed in test tubes to receive implantations of tissue.

(8). In his words, "Enormous and gratifying progress has been made in prolonging life in usefulness and comfort by chemotherapeutic, endocrinological, surgical, and radiological palliative measures," and "research that results in better palliation is significant because of the possibility that by becoming very slightly more effective it will be curative."

Surgery

In the field of surgery there has been a remarkable series of refinements and improvements. Radical surgery has emerged as an important development. Knowledge of the physiological limits of surgery has become more exact. As a result, a great variety of cases that were hitherto considered inoperable and hopeless may now undergo surgery with good chances of survival.

One example of the concept of more radical surgery is seen in a review of the old and the new techniques employed in breast cancer. Previously, the mastectomy removed little more than the breast and the armpit lymph nodes. The surgical concept was enlarged because in numerous instances it was seen that the cancerous lesion spread after surgery. Following extensive research, which revealed that the lymph nodes under the ribs frequently harbor cancer cells, breast surgery began to involve the removal of more bony structure and the lymph nodes under the ribs in properly selected cases.

Many factors other than better operative techniques are also contributing to the continuing

improvements in cancer surgery. Among these are better preoperative and postoperative care, better anesthesia, control of infection by antibiotics and chemotherapy, and control of shock by transfusions.

Radiation

In recent years the comparative advantages of surgery and radiation have been under intensive study, and the question of when to operate and when to irradiate is now better understood. At the same time, numerous technical advances have been made in radiation therapy. In addition to radium, radon, and medium voltage X-ray machines, the radiologist has at his disposal supervoltage X-ray generators, new types of radiation from the betatron and the cyclotron, and a number of new radioactive substances for use in treatment.

Among other advances in the field of radiation, progress has been made in controlling or avoiding radiation burns and radiation sickness. Investigating the problem of radiation sickness, scientists at a number of laboratories are seeking ways to modify lethal irradiation injuries. In collaborative studies with the Argonne National Laboratory of the University of Chicago, Lorenz and his associates at the National Cancer Institute have discovered that intravenous or intraperitoneal injections of bone marrow into mice and guinea pigs enable from 70 to 100 percent of the animals to survive acute lethal doses of irradiation (9). These discoveries may prove valuable in the irradiation

The large tumor on the mouse's flank is a transplant from one of a number of thyroid cancers produced experimentally in mice. The transplantable thyroid cancers provide a valuable new tool for cancer research.

tion treatment of cancer and in improving survival chances following lethal amounts of irradiation, as in atomic warfare.

In the treatment of cancer, the byproducts of atomic research called radioisotopes continue to exhibit increasing utility. Radioactive iodine has been used with good results in some cases of inoperable cancer of the thyroid. Phosphorus and sodium are used in whole body radiation; gallium, in bone tumors. Radioactive phosphorus is used in the treatment of polycythemia vera and certain chronic leukemias; gold is used in cancer and peritoneal and pleural carcinomatosis, and bromine in bladder tumors.

The use of most of these radioactive isotopes requires further experimentation. Better means must be found for localizing many of the isotopes within the cancerous areas, and more effort must be expended in developing radioactive compounds with a high degree of tumor specificity.

Radioactive cobalt appears to show some promise as a substitute for radium. More abundant than radium, radioactive cobalt is relatively inexpensive and will be available through the Atomic Energy Commission to both general practitioners and specialists who

meet AEC standards. Cobalt can be handled more easily than radium and can be fashioned into various pliable shapes, thereby permitting the radiologist greater flexibility in applying dosages.

It must be emphasized that radium therapy is not going out of use. Radium still plays a tremendously important role in cancer therapy throughout the world. Through the radium loan program of the National Cancer Institute alone, 56 hospitals (in 29 States and the District of Columbia) are employing this type of therapy. Early in 1952, Roosevelt Hospital in New York City unveiled a new converging beam projector radium therapy unit. The projector, weighing 5 tons and using 50 grams of radium, has the power of a 20-million-volt X-ray machine. Radium therapy units such as this and the high voltage X-ray machines now in use offer hope for the cancer patient. With these, it is possible to reach cancers which are not amenable to other radiation therapy or for which surgery offers a low cure rate. Such units are designed to increase the effect of radiation therapy on deep-seated tumors.

Anticancer Drugs

Although their present clinical importance should not be overemphasized, one of the most encouraging aspects of cancer therapy is the rapid development of new chemical agents. None has achieved the status of a cancer cure. But it can now be said, in contrast to the dismal outlook of 15 or 20 years ago, that chemotherapy has been established as a valuable and sound adjunct to surgery and radiation.

Some anticancer drugs have had wide clinical trial. Nitrogen mustards given intravenously have produced temporary remissions in patients with Hodgkin's disease, lymphosarcoma, chronic leukemias, and mycosis fungoides. Triethylene melamine, a newer agent, has produced similar effects in Hodgkin's disease, lymphosarcoma, chronic leukemias, and neuroblastoma when administered by mouth. A drug formerly used as an anesthetic for laboratory animals, urethane (ethyl carbamate) has been found useful in the treatment of some chronic leukemias and multiple myelomas. In the treatment of acute leukemia in children, the

folic acid antagonists, notably aminopterin and amethopterin, have caused temporary clinical improvements. Among other drugs showing promise in the treatment of leukemia, there is a new compound, GT-41 or 1,4-dimethyl sulfonyl butane. Temporary remissions in chronic myelogenous leukemia have been obtained through the use of GT-41, Dr. Alexander Haddow of the Chester Beatty Research Institute, London, reported at the Second National Cancer Conference in Cincinnati during March 1952.

A technique for intra-arterial chemotherapy which may become a valuable auxiliary to surgery and radiation in treating cancer has been developed by Bierman at the National Cancer Institute's Laboratory of Experimental Oncology, San Francisco, and by Klopp at George Washington University, Washington, D. C. This technique uses specially designed catheters to inject drugs into close contact with the cancers, lessening damage to normal tissues (10). Administration of agents by the intra-arterial route appears to be quicker and to produce results of longer duration than intravenous injections. Recently there have been successful attempts to employ chemotherapeutic measures to prepare apparently inoperable cancer patients for surgery. Klopp and his collaborators have reported that aureomycin given intra-arterially or intravenously permitted surgery on several cancer patients whose lesions could ordinarily be considered inoperable.

Hormones

Huggins of the University of Chicago was among the first to demonstrate that induced imbalances of hormones might have marked effects on some types of neoplastic disease. He observed remissions in the growth of prostatic cancer following castration and administration of estrogenic substances. Correlative work on carcinoma of the breast by many investigators in the United States and in foreign countries has indicated that the general principles developed by Huggins may obtain in certain cases of mammary cancer. Unfortunately, the beneficial effects of hormones seem to be temporary to the majority of subjects, but there is hope that present studies will lay the groundwork for hormonal cure of certain specific cancers.

Measuring the toxicity of tumor-damaging drugs by injecting them into eggs and observing the effect on chick embryos, one of the early steps in the development of possible anticancer drugs.

Hertz and Cromer have used hormones to prepare patients for surgery (11). Observing the effect of progesterone on carcinoma of the cervix, they found that regressive alterations of the tumor occurred in 11 of 17 cases and that only one patient showed actual tumor progression while under progesterone therapy. More recently, Hertz has been giving intensive doses of a water-soluble form of estrogen to persons with breast and prostatic cancer. Administered intravenously and subcutaneously, these large doses are well tolerated by the body and are reported to be highly effective in activating estrogen therapy. This new technique is under study to see whether it may be more useful than other types of estrogen therapy.

Research on Diagnosis

Because the curability of cancer is closely related to early diagnosis, the problem of finding a good screening test is an urgent one. An ideal solution would be the development of a blood test like the Wassermann—a test which can be applied on a mass basis at reasonable cost and which is specific enough to identify a high percentage of cancer cases at an early stage. At present there is no such general cancer test. Many new tests have been developed and evaluated, but as yet none has been found which is sufficiently sensitive and specific to be practicable.

However, the approach seems hopeful. It is known, for instance, that there are changes in the body chemistry of cancer patients. For example, in some patients with prostatic cancer the acid phosphatase level is increased. Much effort is being expended in this area of research. Among the approaches are physical and chemical analyses of the body fluids, development of certain immunological reactions and many enzymological procedures, and the use of radioactive tracers.

Although a useful general test appears to be still in the future, some of the specific tests show definite promise. One of the most useful is the cytologic examination developed by Papanicolaou of Cornell University Medical College. Briefly, this test consists of collecting exfoliated cells—by aspiration or scraping—from a hollow part of the body; then placing the cells on a glass slide and examining them for possible cancer. The method is particularly useful as an aid to the diagnosis of cancer of the uterine cervix. In the past few years many qualified persons have been trained in the techniques of this test and the interpretation of its results, and at the present time some practitioners are routinely employing this screening procedure in cervical cancer diagnoses.

Although this test is theoretically applicable to any of the body excretions, further experimentation is necessary to determine its general use. From the standpoint of accuracy, the method is applied at present with greatest success in the diagnosis of cancer of the uterine cervix and the lung.

Cancer of the uterine cervix is of great clinical importance. The uterus is the second most frequent site of cancer in the female, and in that organ the disease occurs most frequently in the cervix. Cancer of the uterine cervix is reported to be 75 percent curable in the early stage and 15 percent when moderately well advanced. To determine the case-finding possibilities of the cytologic method in cancer of the uterine cervix, a 3-year study is under way in Memphis and Shelby County, Tenn., in which all women 20 years of age and older will be given an opportunity to have cytologic examinations for uterine cancer at yearly intervals. Supported by grants-in-aid from the National Cancer Institute, this project is being conducted with the

cooperation of the Memphis and Shelby County Medical Society, the Memphis and Shelby County Health Department, the Department of Obstetrics and Gynecology and the Institute of Pathology of the University of Tennessee College of Medicine, and the Memphis Division of the American Cancer Society. (See *Public Health Reports*, June 1952, frontispiece.) Further studies in this field will be done in the cytology laboratory which the National Cancer Institute will operate in the Public Health Service's new Clinical Center at the National Institutes of Health, Bethesda, Md.

Variations of the original cytologic technique have been developed for the diagnosis of cancer of other sites. An abrasive balloon technique has been used with some success in the detection of gastric carcinoma. In this technique the balloon, covered by a fine, silk mesh, is inserted in the stomach, inflated, deflated, and withdrawn. The stomach debris which clings to the mesh of the balloon is examined with a microscope for cancer cells. Although this new diagnostic tool shows considerable promise when used in conjunction with X-ray, it requires further evaluation.

Gastric cancer is the first-ranking cause of cancer deaths among men. The development of a good diagnostic procedure for this type of cancer is essential since conventional methods discover only about one-fifth of the cases at an early stage. Toward this end, Traut and Rosenthal of the University of California have developed another new technique. It consists of washing the patient's stomach with a solution of papain, an enzyme which dissolves the mucus on the stomach lining and thereby frees cancer cells trapped by the mucus.

In the X-ray field at least two tools have been developed which aid the early detection of gastric cancer. Morgan at Johns Hopkins University has adapted the Schmidt camera to photo-fluorography for mass screening to discover gastric cancer. Moon at the University of Chicago has developed a device which combines X-ray and television equipment to give sharp, clear pictures of the dense parts of a patient's body.

Atomic energy research has provided still another approach to cancer diagnosis, that is, the use of radioisotopes as tracers to localize tumorous tissues. The use of isotopes in can-

The new converging beam projector radium therapy unit at the Roosevelt Hospital in New York City.

cer diagnosis rests upon the fact that certain abnormal body tissues concentrate large amounts of specific compounds above that of normal tissues. When these compounds are tagged with radioisotopes, the tissues which require the greatest amount of the compounds can be located with the aid of a Geiger or scintillation counter. Several isotopes appear to be of value in diagnosing cancers of various sites. Of the radioactive isotopes which have been used in their elementary form as diagnostic tracers, the best known is radioactive iodine for the diagnosis of metastatic cancers of the thyroid. Diiodofluorescein dye tagged with iodine has been used successfully in the localization of brain tumors, as has human serum albumin tagged with iodine. Phosphorus has been used with limited success in the diagnosis of cancers of the brain, breast, and testicle.

Cancer Morbidity Studies

The search for a diagnostic test has received much assistance from the rapidly developing field of cancer epidemiology. A number of studies and surveys relating to cancer morbidity

and mortality have been conducted which may provide the answers to such questions as: How many people have cancer? How many can expect to get cancer? What sites in the body are most frequently attacked by cancer? How are age, sex, and race associated with specific cancer sites?

Dorn and his associates at the National Cancer Institute have prepared a series of cancer morbidity studies based on data for 1947-48 and covering 10 major metropolitan areas: Atlanta, New Orleans, Birmingham, Dallas, San Francisco, Denver, Detroit, Chicago, Pittsburgh, and Philadelphia. These studies are particularly valuable since they present comparative data over a 10-year period, each of the areas having been surveyed in 1937-39. Following publication of reports on the individual areas, a United States summary will be prepared. This summary will contain geographic comparisons, interpretations of apparent national trends, and special analyses which are not feasible for individual areas. In general, the studies re-emphasize the importance of the varied programs directed toward achieving early diagnosis and treatment.

Cancer progress has many aspects. One is the drastic and wholesome change in public attitudes. Another important change is that cancer research is at last being supported on a scale that permits concerted, continuous effort. Since the close of World War II, unprecedented support and coordination of cancer research have been provided, research facilities have been increased substantially, and the number of research investigators augmented greatly. Investigation at the basic level is being pursued to an extent unknown just a few short years ago, yielding a gratifying number of advances in fundamental knowledge. The armamentarium of the research investigators has been strengthened by the addition of tools such as the cyclotron, the mass spectrograph, the electron microscope, and the ultracentrifuge. With improvements in cancer diagnostic techniques have come increases in cancer clinics and other facilities for diagnosis and treatment. Cancer surgery has been refined and improved, technical advances in radiation therapy have been achieved, and chemotherapy has been established as a sound adjunct to both. Research has added much information on carcinogens and carcinogenesis which may be useful in the prevention of cancer.

It is doubtful that anyone would venture to say how close we may be to solving the cancer problem. It is a complex and serious one and we must prepare for a long and costly effort. Although false hope must not be placed on preliminary reports and unsubstantiated claims, recent progress indicates that cancer can be re-

garded as a practical, scientific problem which science can solve—and will solve.

Mechanical Air Drying Of Hands Following Preoperative Scrubbing

By PAUL E. WALKER, M.D.

THERE ARE several possibilities of bacterial contamination inherent in the drying of the hands and forearms following preoperative scrubbing. Contamination by dust-carried airborne bacteria is one of these. The degree of such contamination will vary with the amount of circulating dust, duration of exposure, and moisture content of the air. Since most operating room layouts are similar, these factors will probably be fairly constant among different hospitals. Scrubbing techniques differ somewhat, but the differences are not great enough to allow much variation in the elimination of bacteria. It is in the drying of the hands that the greatest possible opportunities for contamination exist. In the use of sterile towels for drying, these opportunities are the greatest. Improper rotation of the towel during drying, the touching of the scrub suit or of the unscrubbed portions of the upper extremities, all offer great probabilities of gross contamination.

It would seem that simple air drying of the hands would eliminate these probabilities of contamination. Such a method further has the advantage of elimination of more costly methods of drying. However, it is slow, physically uncomfortable, and may cause chapping of the skin. It could be followed by dust-laden air contamination in relatively dry operating rooms.

To overcome all these difficulties, it seemed to us that the mechanical air dryer had definite possibilities. Before accepting such a device for use, however, it had to be determined

whether or not the forcing of warm air over the extremities would increase contamination, and whether or not it would be economically practicable. This study was undertaken to determine these two points.

Operation of Machine

The air dryer was a standard model manufactured by a national manufacturer, and was not modified for this study. It is a blower mechanism mounted in a white enamel chassis, operated by a small 110-volt motor which forces a current of air over an electrically heated grid. This current of air is directed through a nozzle downward or upward over the extremities. The switch is operated by a trip mechanism mounted on the front, which can be activated by the shoulder or elbow. This mechanism allows the motor to operate for 30-second intervals, but the time can be modified without difficulty. The machine was mounted at a convenient height on a door in the scrub room adjacent to the scrub sinks. We considered this location preferable to any other because of the high moisture content of the air and because of its convenience. Installation of the machine was simple and was done easily by the station electrician.

A standard scrub routine was adopted. Duration of scrubbing, scrubbing solution, and cleansing of nails was the same before each sample was taken. To further standardize the procedure, only the first scrub of the day for each individual was used. No sterile or antiseptic washes or solutions were used except a .66-percent hexachlorophene soap.

In the study on sterile towel-drying technique, the subject after scrubbing walked to the adjacent operating room where he was immediately given a sterile towel by the scrub nurse. He dried his hands in his usual manner. With the air dryer the arms were dried for 60 seconds under the jet of warmed air, the hands being rubbed together as drying proceeded. (With one man the drying period had to be 90 seconds because of his size and heavy hair distribution.)

Following either method, the hands were immersed in a sterile basin containing 1,000 cc. of distilled water and agitated freely. In the first series the water was allowed to run down

Dr. Walker is chief of surgical services, Public Health Service Hospital, Seattle, Wash.

the elevated forearms into the basin. Since this was thought to be a possible source of contamination from water running over the unscrubbed upper arm, this step was eliminated in the second series.

The laboratory procedure was as follows: A 1-cc. sample was taken from the basin of sterile distilled water and added to 20 cc. of nutrient agar in a sterile flask. This was mixed thoroughly and then poured into a Petri dish. After overnight incubation at 37° C., the number of colonies on each plate were counted and recorded.

Contamination

Air samples for bacterial contamination were taken in two operating rooms and in the scrub room for the first 9 days of the study. Since results were so variable and there was no correlation with the other results, this study was abandoned.

Eleven surgeons and six nurses participated in the first study. The surgeons were mixed staff, residents, and interns. One of the nurses was a novice. As shown in table 1, 77 towel-drying cultures and 77 air-drying cultures were taken from this group.

In this group it is to be noted that if colony counts of 50 or over are considered as gross contamination, then 12 subjects in the towel-drying group were so contaminated and only 3 in the air group. If 100 colonies or over are considered as gross contamination, none of the air-dry group and 9 of the towel-dry group were so contaminated.

In the second series, as shown in table 2, three doctors and two nurses were used, each of whom had 15 air-dry and 15 towel-dry cultures. The technique was modified in this group, as mentioned heretofore, in that the hands only were immersed in the solution.

In the second series group the differences are not so great because the subjects were selected and more experienced personnel whose technique might be expected to remain the same from day to day. Here again, however, if 50 colonies per cc. or over is considered gross contamination, the ratio of towel to air is 11 to 4; in cultures showing 100 or more colonies the ratio is 1 to 0.

If presented somewhat differently and combined as in table 3, the differences are more significant. If colonies showing 50 or more are taken, the ratio of contamination of towel to air is 23 to 7. If colony counts of over 100 are

Table 1. Series I

6	5	5	36	22	14	1	0

¹ Minus sign used to show instances of larger number of colonies by air drying.

Table 2. Series II

Subject	Number of cultures		Average number colonies		Difference	Number of cultures over 50 colonies	
	Towel	Air	Towel	Air		Towel	Air
Surgeon No.:							
1-----	15	15	23	24	¹ -1	2	3
2-----	15	15	0.6	1.6	¹ -1	0	0
3-----	15	15	40	19	21	5	1
Nurse No.:							
1-----	15	15	15	10	5	2	0
2-----	15	15	16	3	13	2	0

¹ Minus sign used to show instances of larger number of colonies by air drying.

taken, the ratio is 10 to 0. It is believed that these figures are probably significant and indicate that gross contamination by the mechanical air dryer is apparently less common than by sterile towels.

Cost of Machine

The cost of the machine was \$140. Installation cost was negligible and installation was done by station labor. The maintenance cost will probably be negligible for approximately 5 years. On the other hand, we estimated that we used in this hospital yearly an average of 10,000 towels for hand drying alone. Laundering cost was estimated by our laundry superintendent as being about \$90 yearly. Replacement due to wear and tear ap-

proximates about 100 towels a year at an estimated cost of \$20. Adding to this the cost of folding and pack make-up, the saving over a period of 5 years is obvious.

The dryer tested can be used satisfactorily in its present form. For convenience, however, the trip mechanism should be adjusted to 90 seconds. The manufacturer has advised us that this can be done without extra cost. For added convenience a foot-operated mechanism could be built. This, however, would add somewhat to the over-all cost of the machine. We considered at first the installation of a filter in the mechanism, but in the light of our studies we do not consider this feature necessary. It would entail certain technical difficulties and added expense that are probably not indicated. Further studies with a filter, however, would be of interest to see if bacterial counts could be reduced still further.

Table 3. Total figures for both series

Number of colonies	Number of cultures	
	Towel dry	Air dry
0-5-----	77	92
5-10-----	21	14
10-20-----	14	18
20-50-----	17	21
50-100-----	13	7
Over 100-----	10	0
Total-----	152	152

Conclusions

1. Bacteriological studies of 304 cultures, taken from groups of surgical personnel after use of a standard scrub technique, showed a probably significant reduction of gross contamination of the hands when a mechanical air dryer was used.

2. The mechanical air-drying technique is less expensive than the towel-drying technique.

Histoplasmin and Tuberculin Sensitivity In Texas Infants and Children

By GILBERT B. FORBES, M.D., and CHARLES C. CHANG, M.D.

HISTOPLASMOSIS, a disease of variable symptomatology caused by the fungus *Histoplasma capsulatum*, was first described by Darling in 1906 (1). The disease has received increasing attention during the past decade. An increasing number of clinical instances of the disease are being recognized. In 1941, a histoplasmin skin test was developed (2, 3). And in 1945 researchers reported that a large number of tuberculin-negative individuals with roentgenographic evidence of pulmonary calcification reacted to the skin test antigen, suggesting that a benign form of the disease exists (4).

Extensive skin test surveys have revealed that the percentage of positive reactors among the young adult population is highest in the Ohio, Missouri, and lower Mississippi valley regions and tends to fall off rather sharply with increasing distance from this area, the values varying from 88 percent positive reactors in Kansas City, Mo., to less than 5 percent in the northwest and extreme southeastern parts of the United States (5-7).

In 1951 histoplasmin skin tests were done on 441 infants and children born in Texas. The

subjects were selected at random from patients on the wards of the Children's Medical Center, patients attending the out-patient clinic, and from the pediatric patients seen at Parkland Hospital and St. Paul's Children's Hospital, all in Dallas, Tex. Infants cared for at a nearby foundling home and older children hospitalized at the Scottish Rite Hospital for Crippled Children were also included. The subjects ranged in age from a few days to 16 years. The skin testing program was conducted during the period from April to August 1951.

Material

The histoplasmin (lot H-42) was obtained from the Division of Chronic Disease and Tuberculosis, Public Health Service. It was in the standardized dilution of 1:100. Tuberculin tests were made simultaneously, using old tuberculin in a strength of 1:1000 (0.1 mg.).

The histoplasmin injection (0.1 cc.) was made intradermally on the volar surface of the left forearm, while that of the tuberculin (0.1 cc.) was made on the volar surface of the right forearm. Separate sets of needles and syringes were used. The reaction was read 48 hours after the injection and was considered positive if the area of induration was 5 mm. or more in diameter, without regard to erythema.

Results

Among the 441 histoplasmin and tuberculin tested children, there were 31 positive histo-

Dr. Forbes is chairman of the department of pediatrics, Southwestern Medical School of the University of Texas, and Dr. Chang is now resident house officer, Willard Parker Hospital, New York City. Dr. Jerry E. Miller, clinical associate professor of radiology of the Southwestern Medical School, interpreted the roentgenographs.

plasmin skin tests and 20 positive tuberculin skin tests, an over-all incidence of 7.0 and 4.5 percent, respectively. Two children reacted to both histoplasmin and tuberculin. The total number and percentage of positive results were further grouped according to sex, group, birthplace, and type of disease on admission to the hospital or clinic (table 1).

Although there are minor differences in both tuberculin and histoplasmin sensitivity among the three groups and between sexes, these differences are not statistically significant. Individuals born and reared in the rural areas of Texas would appear, at first glance, to have a definitely higher degree of sensitivity to histoplasmin than Dallas residents, but this difference also is not significant statistically. Nor is there a significant difference ($P=0.08$) in histoplasmin sensitivity between individuals suffering from some chronic disease and those who exhibited no disease at the time of testing.

Roentgenograms of the chest were taken for each child who showed either a positive tuberculin or a positive histoplasmin skin test, or both. Of the 20 subjects with positive tuberculin tests, 9 (45 percent) had pulmonary calcification. Among the 31 with positive histoplasmin tests, 8 subjects (25.8 percent) had roentgenographic evidence of pulmonary calcification.

In studying the influence of age on both histoplasmin and tuberculin sensitivity, we find a trend toward increased histoplasmin sensitivity as the subjects become older; indeed none of the 94 subjects in the 0-2-year age group exhibited a positive test. The pattern of tuberculin posi-

Effect of age on histoplasmin and tuberculin sensitivity, 441 Texas children

tivity is much less regular and shows no consistent age variation (table 2). The effect of age on histoplasmin sensitivity can be seen better in the chart where the subjects are divided into larger age groups on an arbitrary basis.

Discussion

Palmer observed 21 (34.4 percent) positive histoplasmin reactors among 61 Texas student nurses (6). Christie and Peterson in a survey of histoplasmin sensitivities at Vanderbilt University recorded 7 positive tests (25.9 percent) among Texans (4). Beadenkopf and his associates, working at the University of Chicago,

Table 1. Comparative incidence of sensitivity to tuberculin and histoplasmin related to sex, race, birthplace, and type of disease on admission to hospital or clinic

Number and percentage	Sex		Group			Birthplace		Type of disease		
	Male	Female	White	Negro	Latin-American origin	Dallas	Non-Dallas	Acute	Chronic	None
Total number.....	227	214	258	138	45	228	213	165	225	51
Tuberculin positive:										
Number.....	11	9	13	4	3	13	7	6	12	2
Percent.....	4.8	4.2	5.0	3.0	6.7	5.7	3.3	3.6	5.3	3.9
Histoplasmin positive:										
Number.....	18	13	22	5	4	8	23	9	21	1
Percent.....	7.9	6.1	8.5	3.6	8.9	3.9	10.8	5.5	9.3	2.0

found an incidence of 30 percent among 100 students who had resided in the State of Texas for most of their lives (7). In a study of 200 adults at the Parkland Hospital, Dallas (both in-patients and the hospital personnel were tested), an incidence of 31 percent positive reactors was observed (8). All of these studies were done on adults or individuals in the late teens. Except for Chapman's series, none of the individuals tested were living in Texas at the time the test was made.

Comparison of our results with those reported for children from the St. Louis, Mo., area (9), reveals that the increase in percentage reactors with age is less precipitous in the Texas series. For example the incidence of positive reactors in the 3- to 6-year-old St. Louis group is approximately four times that of the comparable age group of Texas children, and there is a threefold difference in the 6- to 12-year age group. Consequently, it would appear that individuals of all ages have a higher incidence of

histoplasmin reactivity in the St. Louis area than individuals in the region around Dallas.

It is of interest that none of the patients in our series was considered to have clinically manifest histoplasmosis.

Summary

Histoplasmin and tuberculin skin tests were performed on 441 infants and children whose birthplace and principal residence was in Texas. Most of the patients studied lived in Dallas or the immediate surrounding territory. A significant degree of relationship between age and histoplasmin sensitivity was noted.

Public Health in the Western States

By WILTON L. HALVERSON, M.D.

PUBLIC HEALTH services in the western States and Territories have developed remarkably since the organization of the Western Branch of the American Public Health Association 23 years ago.

The rapid increase of the population of the West and the resulting industrial expansion, accentuated by the production requirements of World War II and the present situation, have been accompanied by tremendous health, social, and economic problems, the solution of which is taxing our resources. It requires the best combined efforts of every individual who finds himself a part of the movement.

On the West was placed the responsibility of providing a tremendous amount of war materials, since the war requirements were far greater than the potential capacity of the eastern and midwestern production centers. The danger of overconcentration of industry in any section of the country was an additional and potent reason for the decentralization of the shipbuilding and airplane industry. The West offered labor reserves and natural resources that could not be ignored. California's war contracts, for example, were larger than those of any other State for about 2 years.

With the end of actual fighting and the fulfillment of war contracts, the expected large-scale unemployment and an exodus of workers

to their former homes in the Midwest and the South did not occur. On the contrary, the population increase continued almost unabated. Thousands of war veterans who had spent months in the training camps in the West decided to make the West their permanent home. And industry, quick to see the advantage of manufacturing commodities near the place of consumption, converted war plants to peacetime production.

The public health profession is particularly challenged not only by the problems posed by the physical characteristics of the area, such as the limited water resources in a large part of the West and the rapid industrialization of its centers, but also by the country's entrance into a new phase of scientific development, the atomic age. Atomic development comes at a period when time and space have been compressed by transportation of a speed surpassing sonic limits and a time in history when world peace is uncertain.

What part will the public health profession of the West play in such a time as this? Will we stay with the stereotyped and traditional aspects of our "basic six," or will we stir into an awareness of the problems confronting us now and think and plan for the eventualities of this year and the years to come?

There are many problems for which we must find solutions if we are to discharge the responsibilities society has placed upon us.

Atomic Energy Control

In atomic energy we have probably the most significant and potentially dangerous processes to which society has ever been exposed. Dr.

Dr. Halverson, director of public health of the State of California, is president of the American Public Health Association. This article is based on a paper presented at the annual meeting of the Western Branch of the Association, Denver, Colo., June 1952.

Abel Wolman has pointed out: "In the place of a few radium dial painters doing standardized work . . . thousands of workers now perform hundreds of tasks in the vicinity of materials releasing much more radiation than man has ever known before. . . . Some idea of this total rapid advance may be obtained from the fact that less than 10 years ago approximately 3 pounds of radium were under human control. Today radioactive materials are being produced and in many instances are being used to the equivalent of millions of pounds of radium" (1).

The interest and concern of the public health worker should not await the solution of all of the inherent problems. This may take a long time in such a complex field, and in the meantime hundreds of deaths may take place. Like any other problem, it requires analysis and action on the basis of the best available evidence. The epidemiologist, for example, will in this case be concerned with the amount, type, and period of radiation rather than with the types and virulence of bacterial infection. "The sanitary engineer must think about the number and size of processing units which require water supply, heat exchange, drainage, air conditioning, and ventilating equipment" (2).

Information regarding the distribution of radioisotopes, which has grown from a few hundred shipments in 1946 to several thousands annually, is made available to State health departments by the Atomic Energy Commission. The only information withheld from the States relates to shipments for classified uses.

The Atomic Energy Commission has been careful to supply the user with information regarding toxicity of the materials and the length of safe exposure. In spite of these precautions mistakes can be made and accidents may occur. In California a drum of radioactive cobalt accidentally fell from a truck. Fortunately, it was picked up by students who understood its significance and returned it to the laboratory. In another instance, a medical technician in a southern hospital was conducting analytical procedures with a radioactive substance in a manner which was subjecting her to total radiation of many times tolerance (1).

Are waters used for cooling properly protected from radiation or if exposed are they properly safeguarded? Are industrial wastes

from establishments using these products properly controlled so as to prevent harmful contamination to people in the general area and to life in general? These are questions of prime importance to the public health.

While the information made available to the public has sometimes been overdramatized, the evidence available is sufficient to indicate the great importance of establishing control programs.

This is a field which requires careful exploration before administrative action is taken. California is in the process of this phase of the work. Following consultation with the Public Health Service, the State health department has assigned primary exploratory responsibility to an engineer who will, with the help of a staff advisory committee and other experts, outline a program of control which the department will recommend to the governor and the legislature for action.

Health departments, particularly in the more populous States, can no longer allow events to take their natural course in this urgent problem.

Occupational Health

With the rapid industrialization of the West, we must give greater consideration to, and develop a broader interest in, the health of the worker. Our industrial growth is not simply an increase in size. It also relates to the development of new substances and new processes, the toxicity and potential danger of which in many instances have not been defined.

Hundreds of new chemicals are being introduced to control agricultural and domestic pests. A knowledge of the toxicology of parathion, a powerful and effective insecticide—one of the so-called nerve poisons—is of great importance in the protection of workers both in the factory and in the field. New materials and new methods are coming with such regularity and rapidity that we can apply the simile which so aptly described the golden age of bacteriology—they come like corn popping in a pan. This is truly the age of chemistry and physics, just as the last half of the last century was the age of bacteriology.

At the last meeting of the California Conference of Local Health Officers and of the Cali-

ifornia State Board of Health, we discussed the control of the chemical, lindane, an insecticide that can pass directly from the solid to the gaseous state, the speed of this transfer depending on the temperature of the solid.

An enterprising and well-financed company has developed a business based on the distribution of thermogenerators for the dissemination of lindane or other pesticides in eating places and other closed areas where insects are a nuisance. The question of hazard through inhalation and food contamination immediately confronts us and requires that a decision be made as to whether this method of insect control shall be regulated or prohibited.

So many new occupational health hazards are being introduced that industrial hygiene workers can scarcely become familiar even with the names of the new substances. While we are greatly concerned about the specific occupational health problems that relate to the worker's environment, we are also concerned about his general health and to this end should be developing methods and procedures to make available the various established health services.

It is timely that we think of industrial health in terms of general health, particularly because of the developing interest in chronic diseases and the accumulating knowledge, small as it is at present, about what can be done to prevent chronic disease and to prevent to some degree the premature disabilities these conditions bring about.

Labor and industry are approachable in this matter, and in some instances they are ready to work with public health agencies in developing programs which will conserve the already short labor supply and which can lighten the load of workmen's compensation by protecting the health of the worker through well-planned preventive programs.

Chronic Disease Control

Chronic disease control is a controversial subject in many ways. Can a measurable amount of disability be prevented by early diagnosis and preventive measures? Should health departments be concerned with personal health only as it relates to contagious disease and the special field of maternal and child health? Are multiphasic screening tests profitable and

effective? These elementary questions and many others require practical answers.

The Commission on Chronic Illness, jointly sponsored by the American Hospital Association, the American Medical Association, the American Public Health Association, and the American Public Welfare Association, has stated: "The basic approach to chronic disease must be preventive. Otherwise, the problems created by chronic diseases will grow larger with time, and the hope of any substantial decline in their incidence and severity will be postponed many years" (3).

Weight control is a specific preventive measure related to chronic illness. Public health agencies, both voluntary and official, can unite with other community organizations in planning a program which, if effectively carried out, can add productive healthful years particularly to those above middle age. Several health departments have already initiated such programs and undoubtedly others will marshal their nutritionists, health educators, and other workers to take aggressive action in this area of chronic disease prevention, which lends itself to the mass as well as the individual approach.

Much has been written concerning the relationship of health departments with the private practitioner of medicine. As the years have gone on, most health departments have developed a working relationship with medical societies and with such specialized groups as pediatricians and obstetricians. These working relationships have contributed much to the success of preventive programs. They have convinced most physicians that the purpose of the health department is not to foist "socialized medicine" on the community but to unite with physicians and hospitals in bringing to the community the advantages of preventive services when this is feasible.

In the development of the preventive aspects of the control of chronic illness, this close working relationship is vital. State and local health departments have here a unique opportunity to bring before medical societies the newer developments related to prevention. When this has been done, progress has been made not only in attaining immediate objectives, but also in developing good working relationships in other parts of the public health program.

Here too is an opportunity to develop the interest of a State or local health council. Here is an objective which challenges the interest of almost every family in the community, for a great many have had the problem of caring for a close relative who has spent months or years the living victim of a chronic illness which perchance might have been prevented. It is a problem which each year results in an ever-increasing financial burden to the home, the county, and the State. Public health workers share with the community and private practitioners of medicine the responsibility of finding ways and means to reduce this financial and social burden by the application of preventive measures as they become available.

International Health

In addition to the responsibility we owe to our community, our State, and our Nation, there is an international responsibility. The United States fully supports the program of the World Health Organization, a specialized agency of the United Nations created for the purpose of improving the health of the people of all nations. And for 10 years we have participated in bilateral cooperative health programs in Latin America, administered by the Institute of Inter-American Affairs. Congress has subsequently adopted the policy of providing technical assistance, including health programs, in other underdeveloped countries. In addition to the 17 countries of Latin America, health missions have been established in Liberia, Greece, Turkey, Iran, India, and all of the countries of Southeast Asia. These bilateral programs are increasingly coordinated with the WHO programs (4).

From my own experience in surveying the health and sanitation program of the Institute of Inter-American Affairs, I am convinced that the public health movement in Latin America

has been materially advanced and that there is tangible evidence of appreciation of the help that has been given.

I am also convinced that if the United States is to continue successfully the policy of technical assistance in the field of public health, ways and means must be found to use health personnel of State and local health departments, medical schools, public health schools, voluntary health organizations, private physicians, and all of the other health resources of the various States. Some plan must be developed which will make it possible for health workers to be released for periods of foreign service in order that the programs may be conducted effectively, with credit to the health profession and to our country.

Public health workers can no longer be content and satisfied to restrict their interests to traditional public health services in this country in the face of the crying needs of a world at the crossroads. We must indeed continue to carry on these programs and in addition we must accept the responsibility of developing new and needed programs at home and be willing on call to assist our world neighbors in taking their early steps in the development of health services.

Health Conservation Activities of TVA

By O. M. DERRYBERRY, M.D., M.P.H.

THE WIDELY reported accomplishments of the Tennessee Valley Authority in regional resource development have involved many practical applications of the art and science of modern preventive medicine and public health. It was early recognized that the program would necessarily be concerned with health in two different areas: one, the health and safety of its employees; the other, the impact of its major activities on health problems of regional significance. Responsibility for both interests has been centered in a single administrative unit of TVA, the division of health and safety.

An important factor in TVA's success in the health field as well as in other fields has undoubtedly been the flexible management system under which the program operates. Former Chairman David Lilienthal described the essential characteristics of the system as follows: "... a Federal autonomous agency with authority to make its decisions in the region; ... responsibility to deal with resources as a unified whole, clearly fixed in the regional agency, not divided among several centralized Federal agencies; ... a policy fixed by law that the Federal regional agency work cooperatively with and through local and State agencies" (1).

Dr. Derryberry is director of health of the Tennessee Valley Authority. This paper is a revision of the material he presented at a seminar conducted by the University of Pittsburgh School of Public Health in April 1951.

Employee Health and Safety

Appropriate as objectives of a sound program of employee health and safety services are the "three declared purposes of public health" named by Dr. Haven Emerson and Dr. Thomas Francis, Jr., at an informal conference called in March 1951 to consider future directions of public health. These objectives are "to develop and improve health among our people, to protect them against preventable diseases, and to prolong the average length of life in terms of both quality and quantity."

The TVA employee health and safety program includes preplacement medical examinations, immunization service, periodic health examinations, health education and guidance, prevention of accidents, medical and engineering control of occupational health hazards, and mental hygiene services, along with treatment and rehabilitation of the industrially disabled worker. It is viewed as a dynamic management service undertaken to promote efficiency and economy through the conservation of employee health and as a valuable part of good employee-management relationships. Protection of the health and safety of workers is a responsibility of management recognized by the workmen's compensation laws. Management does not, however, always recognize that provision of this service is also an opportunity to protect its investment in the effective manpower so necessary for successful operation in a highly competitive economy.

To the difficulties ordinarily encountered in the administration of a program embracing these functions must be added, in TVA, the

Vision testing of employees in a powerhouse, a measure which promotes efficiency and aids in the conservation of sight.

factors of dispersion of employees over an area covering 80,000 square miles, a great variety of high-risk occupations in which employees must be carefully placed so that their assignments will be within their physical capacity, and the necessity for developing methods by which the services of State and local health agencies and community medical services may be effectively utilized. At locations where large numbers of TVA employees are concentrated, most of the services are provided through field units operated directly by TVA. The services of local and State health agencies are, however, utilized to the greatest extent feasible. Immunizations, chest X-ray surveys, laboratory service, and communicable disease control are examples of services provided from this source.

Not the least among the tasks to be accomplished in carrying out an employee health and safety program is the enlistment of the cooperation, support, and participation of the operating divisions of the organization. Where supervisors in the construction division, the chemical engineering plant, or the power plant, for example, participate actively in identifying needs for health and safety service and in developing plans to meet those needs, inevitably a better job is done than could be done by the division of health and safety alone. This approach also permits sharing on a broader basis the satisfaction of having determined the need for action and of having taken it.

Sometimes a problem in learning to share responsibility is also encountered within the organization directly responsible for provision of health services. This problem arises principally from the fact that in matters of health the traditional role of the physician has been authoritarian. It is not always easy for him to realize that in preventive and industrial medicine and in public health the medical sciences are but a part of the total technology which must be applied to achieve maintenance of health and prevention of disease and disability.

Services Provided

Figures on the number of services TVA has provided show that its interest in employee health has been realistic. Between November 1, 1933, and July 1, 1952, well over half a million medical examinations were performed; more than 400,000 immunizations against communicable diseases were provided; over a million health maintenance services, including professional consultations, were made available; and about a million job-related injuries were treated. In addition, more than 550,000 clinical diagnostic laboratory services were furnished, and over 90,000 dental hygiene services related to specific occupational disease hazards were given. Until venereal disease treatment was simplified by the establishment of rapid treatment centers and by the provision

Testing hearing of an employee to insure his fitness for work that requires good hearing.

Industrial hygiene laboratory, Wilson Dam, Ala. The section shown is devoted to fluorine studies in connection with the operation of the Tennessee Valley Authority chemical plant.

of widespread services through State health departments, over 100,000 venereal disease treatments were administered.

Some appraisal of the qualitative effect of the services can be made by such observations as the number of employees with physical defects who benefited from occupational placement and the number of referrals and corrections made following periodic health examinations. For example, at one Tennessee Valley Authority construction project 15 percent of the 2,344 employees were selectively placed in jobs having requirements compatible with their physical limitations as determined by employment medical examinations. Periodic medical examinations have found as many as 50 percent of the employees examined to have some condition for which corrective advice or treatment was indicated and referral made. Also significant is the fact that not a single case of smallpox or typhoid has been known to occur at a TVA construction camp.

The accident frequency rate was lowered from 62.5 accidents per million man-hours worked in 1935 to 5.5 accidents per million man-hours worked in 1951. Accident severity was reduced from 6.95 days lost per thousand man-hours worked in 1935 to 1.45 days lost per thousand man-hours worked in 1951. During this time the employee population of TVA varied between about 12,000 and 42,000, with an average of about 15,000. It is a matter of simple arithmetic

to calculate the saving in the cost of accidents effected by these reductions.

The application of the preventive concept to all phases of the development of projects from planning through construction and operation, the masterful job in safety education done by technicians in collaboration with supervisors, and the close integration of the interests of preventive-minded safety engineers and industrial physicians have all undoubtedly served "to develop and improve health among our people, to protect them against preventable diseases, and to prolong the average length of life in terms of both quality and quantity."

Malaria Control

By direction of the TVA act, water control in the Tennessee Valley is undertaken "primarily for the purposes of promoting navigation and controlling floods" and to produce, transmit, and sell power "so far as may be consistent with such purposes." But the effects of water control inevitably are not limited to navigation, floods, and the generation of electric power. Water control, accomplished in the river channel by the construction of dams and reservoirs and on land through readjustments in agricultural practice and extension of forestry development, has had a significant impact on several regional health problems, one of which is the control of malaria.

In 1933, when TVA was established by Con-

Safety on the job. Employees are wearing "hard hats," goggles, respirators. Dust from extensive drilling operations is controlled as necessary by a "wet drilling" process.

Use of helicopter for larvicidal operations (Kentucky Reservoir)—an example of the newer and cheaper methods employed by TVA in the control of malaria. The helicopter is also used for power transmission line patrol during periods when larvicidal operations are not required.

gress, no one had ever heard of an integrated chain of man-made lakes with a shore line of more than 10,000 miles, which is the Tennessee River today. No one had ever envisioned the problem of malaria control on such a vast expanse of impounded water in an area where malaria is endemic. TVA's experience in the progressive development and application of new methods for the prevention and control of malaria on impounded waters is perhaps its best documented and most widely known accomplishment in the field of preventive medicine and public health.

Before TVA came into being, it had been well established that increased prevalence of malaria followed impoundment of waters in areas of the southeastern United States where malaria was endemic unless effective preventive measures were taken. A house-to-house malaria survey made in 1934 in one of the areas of northern Alabama where a TVA reservoir was under development revealed from 20 to 60 percent positive blood films, with an over-all average of about 30 percent positive. There was no escaping the conclusion that malaria was endemic in the Tennessee Valley and that its prevention and control would be a major problem.

TVA immediately accepted its moral obligation to prevent, insofar as possible, the ad-

verse effects of impoundment of water while at the same time promoting the beneficial effects. Using as a guide such State health department regulations governing the impoundment of water as were then in existence, TVA began its program of planning and developing increasingly more effective and economic methods for preventing and controlling malaria. Planning began on the drafting boards, where the water control structures were designed in such a way as to make naturalistic control measures feasible. Other plans included clearing the reservoirs of timber, providing for marginal drainage by connecting marginal depressions with the main body of the reservoir, and developing operating bases for the application of larvicides in areas which were expected to produce the *Anopheles quadrimaculatus*.

These were the principal control measures known in 1933. Subsequent advances included refinements in methods of reservoir preparation; continuous improvements in methods of applying larvicides; development and application of new larvicides; ecological studies of *A. quadrimaculatus* larvae and adults and the establishment of more effective control of mosquito breeding through planned water level management schedules; and development of a reservoir design to facilitate mosquito control. This reservoir design involves determining areas along the margin that can be remodeled by a combination of deepening and filling and other areas that can be diked and dewatered during the mosquito season.

Through all these steps the TVA team of medical malariologist, sanitary engineer, and biologist had the cooperation and support of the official health agencies. Interest in the control of malaria beyond the zone of influence of TVA reservoirs was quick to spring up. Cooperative efforts resulted in the study of the malaria problem on a county-wide basis in all the counties of northern Alabama. Cooperative effort was also responsible for an extensive program of health education, centered around malaria transmission, in elementary schools, high schools, and teacher-training institutions in the sections of the valley where malaria was most prevalent. Time and time again the staff of the State education department, the State health department, and TVA collaborated in

workshop, community health education programs, and demonstration activities.

Reservoir by reservoir the magnitude of TVA's control problem increased. Step by step the TVA team made headway in the improvement of old methods, the discovery of new methods, and the reduction of costs. Ideas first studied in the laboratory were taken into the field for trial if there was the faintest hope of success. Methods withstanding the preliminary field tests were put into effect on an area demonstration basis. Those proving successful there were incorporated into the program of malaria prevention and control, where they held their place only as long as they could satisfy the tests of merit and efficiency. In 1949 and 1950 malaria surveys in selected areas around the most likely mosquito-breeding locations in TVA reservoirs failed to reveal a single parasite-positive slide. Careful field investigations in 1951 and 1952 failed to produce a single case of malaria of natural indigenous origin, although they did reveal a few cases of probable Korean origin.

The general decline in malaria prevalence in the southeastern United States during recent years has relieved considerably the pressure under which TVA has had to carry on its malaria control operations, but it has not led to a relaxation of vigilance nor to false complacency. That smoldering coals of malaria prevalence have been known to flare into disastrous epidemic outbreaks is not new to epidemi-

Remodeled reservoir margins showing filling and deepening work to facilitate malaria control (Wheeler Reservoir in northern Alabama).

Corrosion of turbines due to acid waste in Ocoee River. Pollution in this river has since been largely brought under control.

ologists. TVA has no desire to become newsworthy from neglect of its responsibility to prevent malaria transmission as a result of impoundments.

Stream Sanitation

The conversion of a flowing river into a series of impounded reservoirs and the changes in the chemical, physical, and biological characteristics of water following impoundment provide the basis for TVA's interest in stream sanitation, another regional health problem.

Man has long been torn between a struggle of conflicting stream sanitation interests: one seeking to maintain streams in their natural state of purity; the other attempting to use the streams as a convenient sewer for disposing of the end products of man's physiological and industrial processes. Somewhere a balance among the many reasonable and proper uses of water must eventually be found. Balanced use must take into consideration such items as public or industrial water supplies, fish and wildlife propagation and conservation, recreational activities, power development, flood control, erosion control, discharge of industrial wastes and domestic sewage, irrigation, and perhaps others. Development of a stream sanitation program requires identification of either limited or fundamental conflicts among different water uses, a resolution of these conflicts if possible, and the establishment of a fair, reasonable, and coordinated plan which will achieve and maintain a continuing balance among the various interests.

Safe drinking water on the job is a "must" for TVA projects. Here, a sample of water is being tested at one of the construction projects.

Since 1936, TVA has actively engaged in a program to promote the prevention and control of pollution in the Tennessee River system. The objective has been the protection and general development of the value of water as a basic physical resource of the region. At about the time interest began to crystallize into action, TVA was requested by the State health officers in the valley to undertake a fact-finding survey of the Tennessee River in order to define the pollution problem and obtain the data needed in planning for control. Organized, comprehensive information on the condition of the Tennessee River system was not available, and, furthermore, it was recognized that a program of river development would greatly alter the capacity of the stream to handle pollution.

Critical sections of the Tennessee River and its major tributaries were studied, and surveys of typical industrial plants discharging liquid wastes into the river system were made. As sections of the river system were impounded, the effects of impoundment on stream sanitation were placed under study. Analyses of industrial wastes and estimates of their effect on stream pollution in terms of population equivalents were made; the impact of domestic sewage on the pollution problem was evaluated; the biochemical oxygen demand of various wastes was studied and findings correlated with dissolved oxygen conditions and stratification phenomena in reservoirs. The data compiled can be used to draw a picture of water quality conditions in the river system as they now exist as well as some sketches of what they ought to be from the standpoint of balanced stream sani-

tation interests. From these data can be obtained also some outline of how the job of correction can be done and approximately how much it will cost.

Stream sanitation has been an area of very active collaboration between TVA and other Federal agencies—the Corps of Engineers, the Federal Works Agency, the Public Health Service, and the Atomic Energy Commission. In cooperation with the Atomic Energy Commission, ecological studies are being made in a small tributary impoundment which serves as a stilling basin where certain radioactive wastes are discharged. Collaboration with the Public Health Service, as well as with the States, is currently exemplified by the preparation of several reports on conditions in the Tennessee River Basin. These reports can be most useful to the Public Health Service in connection with its responsibilities under the Water Pollution Control Act of 1948 and will be a valuable aid to those whose duty it is to take corrective and preventive action.

The cooperative effort between the TVA staff and the State health departments has helped to awaken general public interest in stream sanitation in the Tennessee Valley, as evidenced by the passage of legislation relating to stream pollution control in recent years in several of the valley States and by increasing corrective action being undertaken by private industries and public agencies. The job of stream sanitation is by no means complete, however, for many troublesome spots remain. Conflicts between water use interests still exist, and many of the elusive facts concerning the effect of water impoundment on stream quality have not yet been corralled.

Other Health Problems

TVA has also been concerned with such health problems as provision of water supply and sewage disposal systems in its temporary construction villages; sanitary supervision of food-handling establishments serving construction workers living in dormitories; investigation and control of communicable diseases; provision of a safe milk supply; and sanitation of temporary housing developments and trailer camps. These needs have been met largely through close collaboration with official health agencies since

TVA is without authority except on property which it owns and controls. Where there was no organized local health unit in existence, TVA has frequently pooled its resources with those of the local area and of the State health department to help establish or strengthen a full-time local health department. As TVA construction wanes, the support of these services is in most instances being assumed by the communities and the States.

Though many of these health problems have been transitory, TVA has remained in the public water supply business on a large scale. It presently operates 30 water treatment plants at TVA dams and reservations. To the greatest extent feasible, TVA relies upon official health agencies to supervise these installations but must itself maintain a degree of surveillance over them in order to discharge its responsibility for protection of employees and the visiting public. Similarly, most of the services to recreational developments along TVA lakes have now been taken over by local health departments.

Another health problem to which TVA is giving attention is that of atmospheric pollution. In developing plans for new steam-operated generating plants to meet the increasingly urgent demands for power in the Tennessee Valley, TVA is giving careful study to

the potential problem which may be associated with the discharge of fly ash, fumes, gases, and other waste materials so that necessary controls may be included to the greatest extent possible in plant design and construction.

Flexibility and Progress

The events and activities described here were not all, of course, the result of a perfect plan completely conceived in the beginning of the Tennessee Valley Authority. It is doubtful that anyone envisioned all the ramifications which have been a part of the program. Without question, a major factor contributing to TVA's success in dealing with a multiplicity of related interests has been the flexible management scheme at the heart of TVA. With authority and responsibility for leadership in the unified development of the resources of the region clearly fixed in a single agency, the many and complex technical and social problems have been boldly engaged. The result has been outstanding progress in the promotion of human welfare in the Tennessee Valley.

Special Notice—PHR Free and Personal Subscriptions

Free subscriptions to *Public Health Reports* are available primarily to official and nonprofit health and medical agencies, educational and professional institutions, and related groups concerned with the public health. This distribution is almost entirely on the institutional rather than an individual basis.

Agencies not eligible for free distribution, and individuals, may purchase annual subscriptions for \$4.25 (75 cents additional for foreign mailing). This will cover the costs of mailing the 12 monthly issues and the annual index. Copies of most of the 1952-53 issues and the 1952 index are available to new *paid subscribers* as long as the supplies last. To get them, mention this notice when placing orders with the Superintendent of Documents, Government Printing Office, Washington 25, D. C. Enclose check, post office money order, or Government Printing Office coupons. Do not send currency or stamps.

Copies of back issues are available to current free and paid subscribers, also, to fill out incomplete volumes. The request should be made directly to the Public Health Service.

Insect and Rodent Control In Epidemics and Disasters

By JOHN S. WILEY, M.S.E., and PORTER A. STEPHENS, B.S.

VECTOR-BORNE diseases are an added hazard to humans when, in the wake of floods, storms, earthquakes, fires, and wartime destruction, insects and rodents increase in number. The public health officer should, imme-

Mr. Wiley, a senior sanitary engineer in the Public Health Service, is assistant chief of the vector control and investigations branch of the Communicable Disease Center, where he was in charge of typhus control activities from 1945 to 1949.

Mr. Stephens, a sanitary engineer in the Reserve Corps of the Public Health Service, is with the disaster aid and facility planning unit of the Center's vector control and investigations branch. Since 1942 he has been actively engaged in malaria and typhus control and last year was consultant to the Service's regional medical directors on flood-induced mosquito problems in Nebraska, Iowa, and Utah.

diately after a disaster, or when an outbreak is or may be imminent, evaluate potential hazards from insects and rodents and prepare a plan for controlling them. The danger of disease may not be confined to areas in which there has been a history of malaria, typhus, plague, dengue, or yellow fever. Fly-borne diarrheal diseases, mosquito-borne virus encephalitis, and such rodent-borne diseases as leptospirosis (Weil's disease), rickettsialpox, and lymphocytic choriomeningitis may also occur.

Disasters often disrupt normal sanitation and public utility services and result in temporary relocation of displaced persons. Evacuation of personnel to save lives, application of first aid and medical care, and provision of shelter, safe water, and food are of first importance. Rehabilitation is next in importance to restore normal life to the community. Concerted efforts are required to remove debris and repair buildings and utilities, and to prevent the development of pests, the insects and rodents which carry diseases and seriously affect community activity.

Flies, mosquitoes, and rats, present in most parts of the United States, are hosts and carriers of many diseases in aftermaths of disasters. Especially as flood waters recede, these insects and rodents may multiply in unprecedented numbers.

A number of vector-borne diseases may occur in epidemic proportions, particularly after a build-up of the vector populations following a disaster (see table).

The potential build-up of the insect and

Collapsed building and debris resulting from floodwater.

Disposal of flood damaged meat.

rodent vectors depends upon a number of factors: the type and magnitude of the disaster; its geographic location; the season of the year; and existing control measures or the timing of emergency measures for combating the pests.

Fires, floods, and other disasters may temporarily reduce rather than increase the numbers of vectors and pests by killing them or destroying their breeding and harborage areas. However, disasters generally increase the breeding potentials by creating larger breeding and harborage areas. Midwest floods in the summer of 1951 and in the spring of 1952 created extensive water areas suitable for mosquito breeding and left volumes of organic matter in which flies and rats could develop in large numbers.

The geographic location of the disaster area is, of course, a factor determining the danger from specific vector-borne diseases. Malaria, typhus, dengue, and yellow fever would not be expected to develop to epidemic proportions in northern sections of the United States. This may be due to a lack of host or vector, to the absence of infection among inhabitants, or to other conditions which prevent these diseases from spreading. *Anopheles* mosquitoes, *X. cheopis* fleas, and rats all exist in these sections of the country, but their presence would not be expected to result in an epidemic threat of the tropical or semitropical diseases. In southern areas, however, malaria and typhus would be real threats. If a source of infection were introduced, plague, yellow fever, and dengue could break out. Pestiferous insects and rodents may develop in large numbers following a disaster in almost any part of the United States.

The season of the year greatly affects the ex-

Entomologist surveying residual floodwater for mosquito production.

Space spraying of insecticides for fly control.

tent to which vectors and pests develop. Certain fly and mosquito species have short breeding seasons, particularly in the North where normally they do not develop intensively. However, myriads of insects may develop following a disaster during the breeding season, no matter how short it may be.

Whether insect or rodent control measures are warranted, following disasters or during epidemics, depends upon the factors discussed. The period of development may be from 7 to 10 days in the case of mosquitoes and flies. It is therefore essential that entomological surveys and plans should be made as soon as possible after a disaster in order to have personnel, equipment, and materials available as the problem develops.

In a public health insect or rodent control emergency program following a disaster, whether it be to control an epidemic or to prevent disease and discomfort, the State health officer or his designated representative functions as coordinator of all health activities within the State. If the assistance of the Public Health Service is desired, it should be requested of the appropriate Public Health Service regional office by the State health officer. All insect and rodent control measures should be coordinated to secure efficient program supervision. Chemical control measures may vary for each insect or rodent group. Control by sanitation is equally as important as chemical control and may effectively and simultaneously reduce the number of types of vectors. The en-

tire activity should be supervised by a single individual competent in this field of work.

Three brochures have recently been issued by the Communicable Disease Center of the Public Health Service on fly, mosquito, and rodent control in epidemics and disasters (1-3). They deal in some detail with the various recommended control measures which in this article are considered only in a general way.

Fly Control

Required conditions for fly control may be summarized as: (a) during an epidemic of diarrheal disease in an area which has a large fly population or where seasonal breeding will soon begin; (b) following a disaster which occurs during or just at the beginning of the fly-breeding season and which has disrupted the sanitation facilities for disposal of fecal matter and other organic wastes; and (c) under particular conditions related to diseases where transmission by flies is possible.

The health menace and discomfort from flies result from lack or failure of sanitation facilities; therefore, augmentation of these facilities is of primary importance. Vehicles and manpower should be made available at the earliest opportunity for sanitary storage, collection, and disposal of accumulated human excrement and other organic wastes resulting from a disaster. For the control of diarrheal diseases, flies should be excluded from excreta and from human food, which indicates the need for fly-proof disposal pits and for screening of temporary and per-

Disease	Source of infection	Vector
Malaria.....	Man.....	<i>Anopheles quadrimaculatus</i> . <i>Anopheles freeborni</i> <i>Anopheles albimanus</i> .
Dengue.....	Man.....	<i>Aedes aegypti</i> .
Yellow fever.....	Man.....	<i>A. aegypti</i> .
Virus encephalitis.....	Bird, possibly horse.....	<i>Culex tarsalis</i> and other mosquitoes.
Diarrhea and dysentery.....	Man.....	Domestic flies and rats. ¹
Murine typhus fever.....	Rats.....	<i>Xenopsylla cheopis</i> (fleas).
Plague.....	Rodents, man.....	<i>X. cheopis</i> and other fleas. ²
Lymphocytic choriomeningitis.....	House mouse.....	Possibly arthropods occasionally. ¹
Rickettsialpox.....	House mouse.....	<i>Allodermomyssus sanguineus</i> (mite).
Leptospirosis.....	Rats, less often dogs.....	(³).

¹ Transmission also through contaminated food or dust. ² Also transmissible from man to man. ³ Transmitted through the skin, or water contaminated with rat urine or feces.

Adult and larval stage flies produced from animals drowned by flood.

Mixing poison bait for rodent control

manent food-handling establishments. Despite the efficacy of improvised methods to restore sanitation facilities, it is probable that the use of chemicals will be required to (a) supplement the sanitation effort, or (b) abate fly populations until adequate sanitation is restored.

Mosquito Control

In mosquito-borne disease transmission, initial control measures should be directed against adult mosquitoes as the quickest means of intercepting the course of the epidemic. Residual

spraying with a DDT formulation on interior surfaces of occupied dwellings, and sometimes of outbuildings, will effectively destroy the house-frequenting species of recognized disease vectors. Space spray measures may be indicated in certain instances. Larviciding may be necessary to prevent the development of further broods following a disaster.

The current epidemic of mosquito-borne encephalitis in the Central Valley of California furnishes a striking example of the importance of emergency mosquito control measures.

Rodent Control

In the event of a rodent-borne disease transmitted by arthropods, control of the fleas or mites is of first importance. DDT dust applied to rat runs and harborages will effectively reduce the ectoparasites. Rat poisoning is applied to control the rats after the DDT has had an opportunity to kill the ectoparasites. With warfarin, the poison and DDT may be applied concurrently. In the case of diseases transmitted from rat to man without vectors, rat poisoning is instituted immediately without previous insecticide application. If rodents already heavily infest the area, it is important that a relatively quick-acting poison be used before attempting to clean up and restore sanitation. If rats have migrated or concentrated in the disaster area, it may be necessary to move the people to a rat-free area. Finally, the removal of rubbish and debris, and the proper storage and disposal of garbage will deprive remaining rats of food and shelter.

The Positive Approach To a Tuberculosis Nursing Program

By DORIS E. ROBERTS, R.N.

THE MODERN attack on tuberculosis has made tangible inroads on the control of this disease and gives us reason to look forward to the day when tuberculosis will no longer be a major public health problem. The decline in the tuberculosis death rate, from 45.8 per 100,000 population in the United States in 1940 (1) to 22.5 in 1950 (2), is one evidence of change for the better. We are discovering an increasing number of cases in the earlier stage of the disease; we have more hospital beds for tuberculosis patients than ever before; treatment methods are improving; and rehabilitation services are expanding. Health workers can have a more optimistic attitude toward tuberculosis control today than they could even as recently as 1940.

But we must remember that as the problem itself is lessened, the challenge it presents to health workers is intensified. This means that we must evaluate what we are doing in terms of productive action and revise our thinking and procedures to conform to modern concepts.

Administrative Policies

How can nursing programs be adapted to fit this changing pattern of tuberculosis control?

Miss Roberts, nurse officer with the Division of Chronic Disease and Tuberculosis, Public Health Service, presented this paper at the annual meeting of the Philadelphia Tuberculosis Conference, October 31, 1952.

The positive approach to tuberculosis problems calls for enlightened administrative policies. Policies for tuberculosis control must be flexible enough to permit individual evaluation and application to each family situation. They must also change as changes occur in the needs of the patient and the community. They must give practical consideration to the available personnel and facilities to assure beneficial and economical use of all services. This is possible only when plans are made jointly by all those responsible for the various activities of tuberculosis control. For example, some health departments have been able to establish the policy that at least one public health nursing visit be made to the home of every reported new case of active tuberculosis. Such a policy affects many relationships and services of the health agency. Therefore, before a policy is established its need and broad implications must be considered by the health officer, the tuberculosis control officer, and the public health nursing director. They must make certain that the policy conforms to the responsibilities and objectives of the agency, and, simultaneously, they must make plans for it to be carried out.

Many more public health nurses are needed to meet community demands for nursing services in the home. With services for home care and care of the chronically ill expanding, we can expect the demand for nursing services also to increase. This means that policies regulating the discharge of patients from nursing service are as important as those relating to the admission of patients for care. Plans for care must give consideration to the laws of learning

so that the most intensive nursing service is brought to the family at the time the family's desire and need for learning is greatest. Work responsibilities given nursing personnel must be carefully evaluated in order to assure the best use of the education and skills of professional nurses.

Serious shortages in nursing personnel are frequently reported by tuberculosis hospitals. Yet in these hospitals it is not infrequently found that personnel policies lag behind those in the local general hospitals and health agencies, that facilities are inadequate for the protection of hospital personnel, and that the limited amount of professional nursing time is being used in the housekeeping, pharmacy, and dietary departments. Solution of these problems requires intelligent planning at the administrative level.

National organizations and committees have recognized some of the common administrative problems and have made recommendations for their solution. The Tuberculosis Nursing Advisory Service recently published "Cues to Staffing Tuberculosis Units in Hospitals" (3), which should help hospital nursing administrators to evaluate and plan for nursing service to patients. The American Trudeau Society has appointed a committee to study the hazards involved in tuberculosis nursing. We can look for the recommendations of this committee to assist us to make sound plans for the protection of patients and hospital personnel from tuberculosis infections. A subcommittee of the American Public Health Association's Committee on Administrative Practices is developing a guide for the medical and public health nursing supervision of tuberculosis cases and contacts (4), which should assist health departments in selecting tuberculosis families in need of nursing service and in determining the amount of service they need.

These guides are administrative tools which must be adapted to meet local needs and situations, if they are to be used effectively.

Coordination of Services

Included among the community resources which contribute to the effectiveness of nursing

in general, and tuberculosis control are the medical care, social welfare, and rehabilitation facilities. It is important to bring these services into their appropriate supportive relationship with the agencies responsible for tuberculosis control. Through such coordination we can stimulate new interest and more active participation on the part of individuals and agencies unaware of their responsibilities in the tuberculosis control program. And, more important, we can find renewed vigor in attacking this disease. For example, many general hospitals are participating in case-finding activities by X-ray examinations of all clinic and hospital admissions, a group with a high incidence of tuberculosis. Many hospitals which previously refused to admit tuberculosis patients are now taking a more realistic view of their part in tuberculosis control. They are admitting tuberculosis patients and giving them at least immediate care until provisions can be made for long-term care. Also, because the hospitals identify the tuberculosis cases, they can carry out appropriate isolation procedures to prevent the spread of the disease to other patients and to hospital personnel.

In many areas tuberculosis hospitals and health departments are coordinating their efforts so that patient care is becoming an unbroken course from the point of discovery of the disease to complete rehabilitation. To assist in the coordination of services, some health departments employ personnel who work as liaison between the hospital and public health agencies. And some health departments have revised interagency transferral forms to include more comprehensive information about the patient and family so that patient supervision and care can be better integrated.

Nursing Education and Service

Just as good administration and coordination of services are essential to a positive nursing program, so is the provision of nursing consultation. The activities of the tuberculosis nursing consultant may vary considerably but should always include participation in the program planning and in the evaluation of services. She is the technical adviser and therefore should be able to see the many activities of

nursing in their proper perspective to the total control program. Thirty-four States now have tuberculosis nursing consultants, six of whom have extended their consultation services to hospitals as well as to public health agencies (5). In many instances it has been the nursing consultant who has been instrumental in bringing about improved services for patient care, broadened and intensified nursing education in tuberculosis, and improved clinic facilities. She has also helped to resolve inconsistencies in nursing practices in the hospital and in the home.

Our modern tuberculosis control program demands good supervision. In this the nursing supervisor (the public health nursing supervisor or the head nurse in the hospital) makes her important contribution. Her function is to make certain that the program is carried out as planned. She is the middleman between the director and the staff nurse. Through her interpretation of the staff nurse's problems she brings a realistic and practical approach to the director. In her work with the staff she is part educator, administrator, and adviser. Through her, skilled nursing care is provided to the patient and family.

The education of the student and graduate nurse in tuberculosis nursing has often been too limited or lacking. Recognizing that every nurse needs preparation in this field of nursing, schools of nursing are revising their curriculums to meet this need. A report of the Joint Tuberculosis Nursing Advisory Service (6) showed that 39 percent of all schools of nursing are now including tuberculosis nursing in the curriculum. We still have a long way to go. Education is basic to service, and we cannot be satisfied until all schools of nursing include clinical experience in tuberculosis with classroom instruction. This will be possible when more general hospitals accept tuberculosis patients and recognize every patient as an opportunity for student experience; when more tuberculosis hospitals are prepared to offer affiliation programs to schools of nursing; and when more public health agencies are able to accept students for field experience. To make up deficiencies in student nurse education, States have sponsored tuberculosis nursing work conferences and have offered this educational

program to all nurses in the State. These institutes have been sponsored jointly by tuberculosis associations, nursing organizations, and health departments. They not only have contributed to nursing education but have also made it possible for nurses in all areas of work to come together and think through their responsibilities in tuberculosis control.

Finally, it is the staff nurse—in the hospital, the public health agency, the school, the doctor's office, and industry—who gives direct service to the patient, the family, and the community. The effectiveness of the nursing service ultimately rests with her. And she can bring skillful, understanding, complete service to the community in which she works only if she has the security which comes with adequate professional preparation, well-planned supervisory and consultative guidance, and good administrative policies, and only if there are those other facilities and services available in the community which are essential to total patient care. Working within this framework, the staff nurse effectuates a positive approach to tuberculosis nursing.

Capillary Tube Technique For Serologic Screening Of Syphilis

By CHARLES R. FREEBLE, JR., M.D., M.P.H.,
and BERTTINA ORSBURN, B.S.

THE NEED for a simplified method of obtaining blood specimens has been indicated by field observations in the venereal disease control program of the Ohio Department of Health. Obtaining blood by venipuncture is difficult on infants and small children, is objectionable to many adults, and is not suitable for use in the home. For these reasons we have been searching for a method of collecting capillary blood which would give laboratory results of significance.

A number of methods for the collection of small amounts of blood have been tried in the past, especially in pediatric work. The capillary tube collection method as reported in this paper was described by Davies (1) in 1938, and has been in use for several years in various pediatric hospitals, including Children's Hospital in Columbus, Ohio. It is surprising to us that this technique has not been applied more widely to public health work as it appears to have advantages over venipuncture for mass studies as well as for work with infants and children.

Method of Collection

The tubes used for collection of blood are cut in 8-cm. lengths from strong-walled glass tubing of approximately 2-mm. inside diameter, 4-mm. outside diameter, and 1-mm. wall thickness. These 8-cm. tubes hold approximately 0.4 ml. and can readily be filled two-thirds or three-fourths full by capillary action with blood from finger puncture, or from heel puncture on infants.

Dr. Freeble was formerly chief of the communicable disease division, Ohio Department of Health, Columbus, Ohio. Mrs. Orsburn is a medical technician with that division.

ture on infants. The ends of the tubes are capped with No. 3-68 M. S. rubber vial stoppers which fit snugly on this diameter tubing, seal the tube well, and protect it from breakage if dropped. This length tube fits an ordinary mailing container and can be safely transported to the laboratory in a routine way.

The finger or heel is cleaned with alcohol, wiped dry, and a fairly deep stab made with a Bard-Parker No. 11 blade mounted in a cork. The capillary tube is filled with blood as described by Davies (2), holding the tube horizontally or tipped slightly downward, and allowing the blood to run into the tube by capillary action. It is not difficult to obtain the necessary amount of blood if the finger is wiped completely dry at the beginning, gentle pressure applied to allow the blood to well out in large drops, and the end of the tube touched to the drop of blood. The tube should not be held against the skin of the finger as this tends to let the blood run down the finger. When filled, the tube is capped at both ends with the vial stoppers. The tubes are numbered with 1-inch Scotch "Wetordry" masking tape No. 202 stamped with a Bates numbering machine. This tape does not loosen or come off in the water bath nor do the stamped numbers, when once dried on the tape, run or fade in the water.

Method of Testing

Before the tubes are placed in the centrifuge, blood clots are loosened with a strong wire 6 to 7 inches in length, and the tubes are then centrifuged at 2,000 rpm for 10 minutes. Following centrifugation, the entire specimen is inactivated in a water bath at 60°-62° C. for 3 minutes. It is not necessary to separate the serum from the clot for inactivation, and handling the blood in this manner conserves the serum and saves time in operation. The tubes are divided into lots of 10 in 250-cc. beakers, and the beakers are filled with water from the water bath to a level which covers the serums. The beakers are then placed in the water bath for inactivation. If the vial stoppers on the ends of the tubes are sufficiently tight no water enters even if the water level in the beaker is above the tops of the tubes.

When removed from the water bath, the tubes

are set out in drilled wooden racks. Divided racks with separated shelves do not work well with these capillary tubes, as the flanges on the vial stoppers tend to catch and pull off when the tubes are put in and taken out of the rack.

Sixteen-gauge glass capillary tubing (approximately 2-mm. outside diameter) in 6-inch lengths, holding 0.2 ml. serum, is used to remove the serum from the collecting tube. With a red wax pencil, a mark is placed 1.5 inches from the end of the tube to measure 0.05 ml. serum for the VDRL test. Some workers consider this length tubing difficult to handle. A shorter length, such as 3 inches, may be used. Sixteen-gauge tubing fits snugly into the smaller opening of a vaccine bulb (for example, bulbs used with smallpox vaccine sets). Using a vaccine bulb, a suction apparatus may be improvised to aid in withdrawing serum from the collection tube. The large opening in the vaccine bulb snugly fits the end of a small glass adapter (7-mm. outside diameter). Attaching a rubber dropper top from an ordinary typing serum bottle to the other end of the adapter completes the apparatus. Other workers have nicknamed this set-up a "squee-gee." With a squee-gee and marked tubing, 0.05 ml. of serum is removed from each sample and placed in a depression of a Boerner micro slide or paraffin ring slide (5).

The antigen is prepared and used as in the standard VDRL technique (4), one drop of antigen from a tuberculin syringe with a 22-gauge needle (1/60 ml.) being added to each serum sample. The plates are then rotated for 4 minutes at 180 rpm on the Boerner rotator. Tests are read as positive, weakly positive, or negative as described in the VDRL technique.

Results

Venous and finger puncture blood specimens were collected simultaneously from 622 patients and employees of the Central Ohio Rapid Treatment Center. Standard Kahn, Kline, Kolmer, and quantitative Kahn tests were done by the laboratory of the Ohio Department of Health on the venous bloods. Capillary VDRL tests on the finger specimens were done at the rapid treatment center.

Of the 622 bloods tested, 397 (63.8 percent) gave positive results with all methods used, 91 (14.6 percent) gave negative results, and 134 (21.6 percent) showed varying disagreement. Table 1 compares the results of the capillary VDRL test with the results obtained from the Kahn, Kline, and Kolmer tests. Best agreement was obtained with the Kline tests.

Complete disagreement occurred in results of tests on 134 serums: The capillary VDRL test

Table 2. Diagnostic status of individuals tested by the capillary VDRL tests and by other methods

Capillary VDRL negative Kline, Kolmer, Kahn, positive		Capillary VDRL positive Kline, Kolmer, Kahn, negative	
Diagnosis	Number of cases	Diagnosis	Number of cases
Early latent, with treatment.....	2	Primary, darkfield positive.....	2
Late latent.....	1	Early latent, with treatment.....	1
Late latent, with treatment.....	3	Late latent, with treatment.....	2
No venereal disease.....	1	Chaneroid.....	1
Total.....	7	Total.....	6

and the other three tests in 13; the Kline in 7; the Kolmer in 6; and the Kahn in 72. On 36 of the 134 specimens, two of the tests were positive and two were negative. Table 2 presents the diagnostic classification of the 13 individuals whose serums when tested by the capillary VDRL were in total disagreement with the other tests.

Five hundred and forty-three (87.3 percent) of the 622 individuals tested were diagnosed syphilitic and 79 (12.7 percent) nonsyphilitic. The capillary VDRL was positive in 499 (91.9 percent) of the 543 diagnosed cases and negative in 77 (97.5 percent) of the 79 nonsyphilitics. Of the 44 syphilitics whose blood was negative to capillary VDRL, 32 were previously treated patients; 9 had primary syphilis; 2 late latent, and 1 central nervous system involvement.

Results of the various tests on the 622 patients and personnel at the Central Ohio Rapid Treatment Center, by syphilitic status, are presented in table 3.

Serums of three individuals among those diagnosed as nonsyphilitic gave positive tests. Two of these had diagnoses of apparent false positive serologic reactions due to recent immunizations. The third had chaneroid, with a further diagnosis of possible primary syphilis, the final diagnosis depending upon further study.

Primary syphilis was the diagnosis in 32 individuals in the series. Of these, 12 were positive and 13 were negative to all tests. Of the seven remaining, six were positive to the capillary VDRL test. Table 4 presents the results of the four test methods on the seven patients having primary syphilis, when test results did not agree completely.

From these results, it appeared that capillary blood collected and tested in the manner described gave results which compared favorably with the results of standard serologic tests on venous blood.

There remained the problems of investigating the suitability of the collection method for mass

testing and of determining the time necessary for a person untrained in this technique to develop proficiency in securing specimens.

By arrangement with the Zanesville City Health Department, Zanesville, Ohio, the collection technique was used in a mass survey conducted by that department among students of the two local high schools as a part of their health course. A team consisting of the junior author, two physicians, and two nurses who had never before used the method secured blood specimens from 1,106 students. The inexperienced collectors developed proficiency after collecting approximately 25 specimens and only 3 of the 1,106 specimens were later found unsatisfactory for testing. Six positive and weakly positive results were obtained, and follow-up observations disclosed three previously undiagnosed, untreated students with congenital syphilis, one who had been previously diagnosed and treated, and two with seemingly false positive reactions, who are still under study. Following this, 94 children in a Columbus Children's Home were tested. Their ages ranged from 4 to 12 years, and all tests were negative.

Somewhat more time was required to obtain specimens by capillary tube than by venipuncture, but when the time consumed in preparing

and sterilizing venipuncture equipment was considered, the time differential disappeared.

Discussion

The method of collecting capillary blood specimens described here, which is essentially the same as that reported by Davies in 1938 (1), may be useful in a venereal disease control program. Using the VDRL test, significant results were obtained on 622 specimens when evaluated according to the stage of syphilis in the persons tested. Field experience in which 1,106 specimens were collected demonstrated the technique to be efficient and economical. Experience with 94 children has demonstrated the advantages of this technique over venipuncture.

Summary

1. A method for collecting capillary blood and testing for syphilis has been discussed. The method combines the advantages of collection by finger puncture and adequate laboratory results.

2. It is suggested that the method can become a useful tool in venereal disease control programs, particularly in regard to the screening of infants and children.

Identifying Common Flies

By HAROLD R. DODGE, Ph.D.

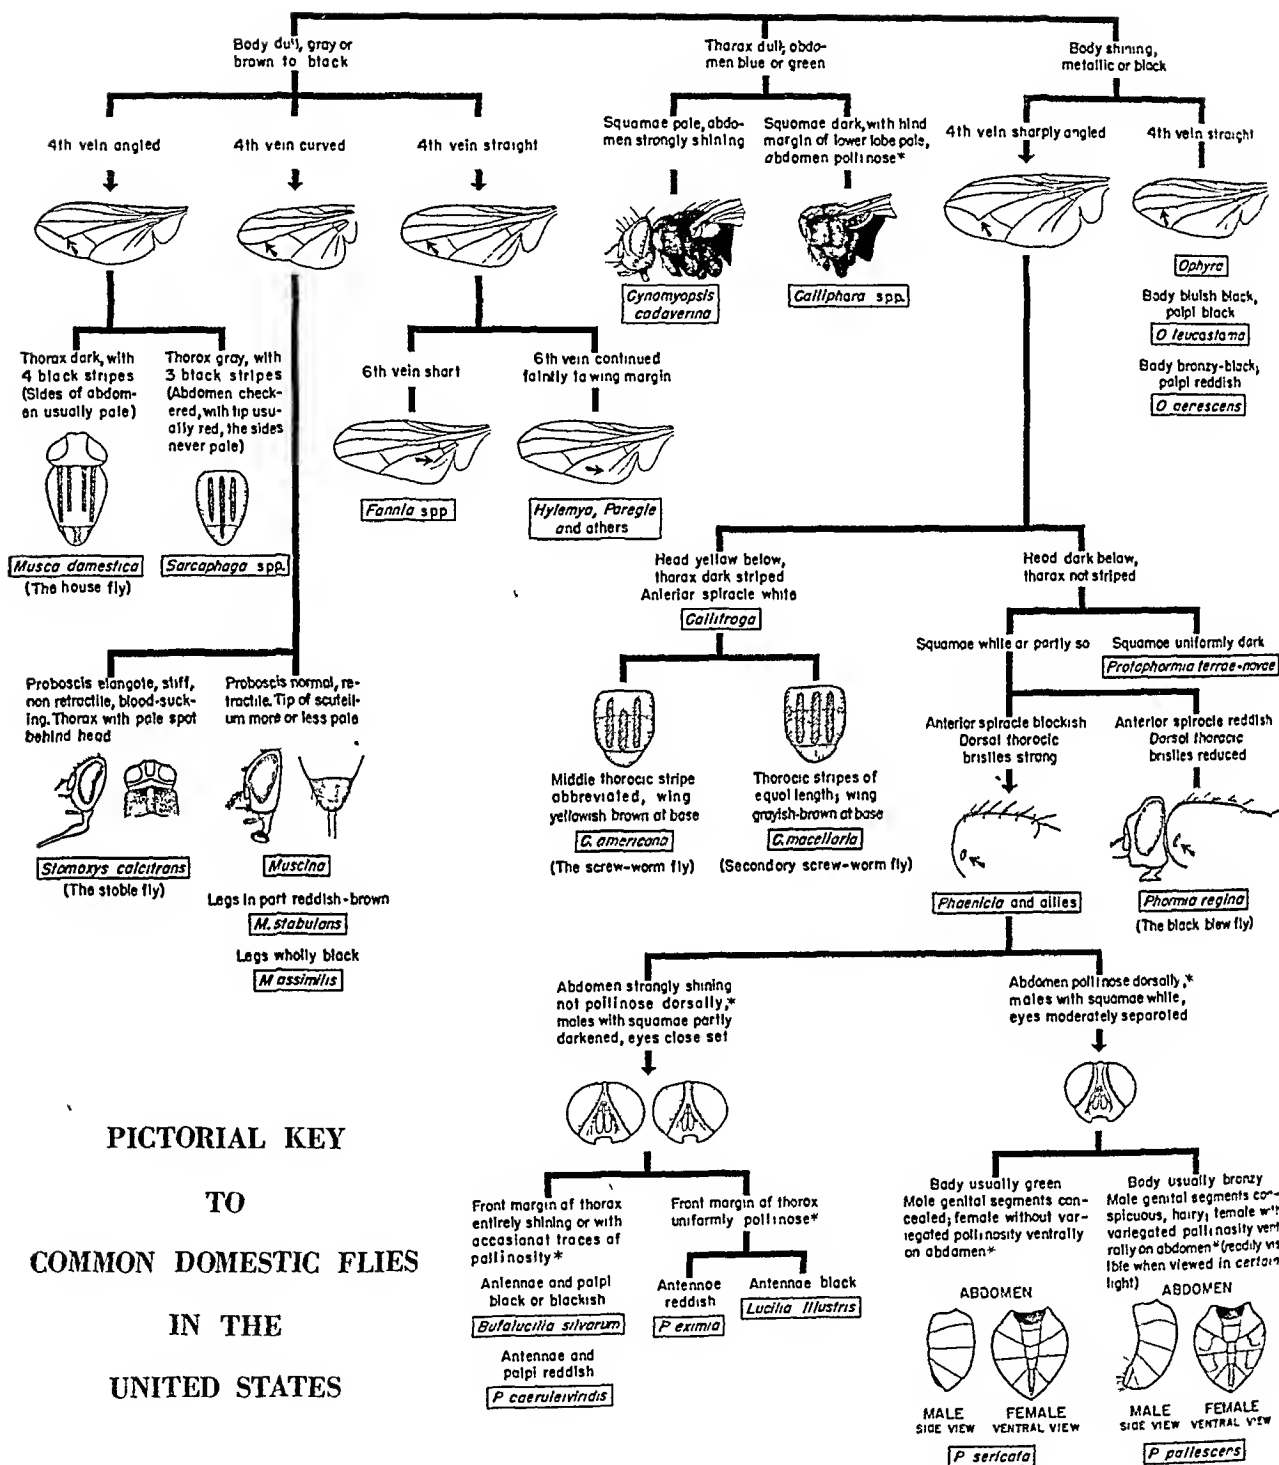

Much of the entomological literature on fly identification is difficult and expensive to obtain. However, the various species of domestic flies in the United States have distinguishing characteristics that workers who lack professional entomological training may learn to recognize. This article is especially designed for the information of personnel engaged in survey and control operations in which large numbers of specimens are involved and the principal objective is measurement of fly densities. Some remarks on zoological terminology and the use of keys are included to aid those not experienced in insect identification. Copies of the two keys on fly identification mentioned in the article and the other available pictorial keys may be obtained by writing the Officer in Charge of the Communicable Disease Center, Public Health Service, Atlanta, Ga.

DURING THE past 6 years, the Communicable Disease Center of the Public Health Service has prepared a series of pictorial keys to facilitate the recognition of insects and other arthropods of medical importance. Two keys have been prepared for the identification of flies. One, the "Pictorial Key to Common Domestic Flies in the U. S.," separates 21 species of common flies, many of which are widely distributed in other parts of the world. The other, the "Pictorial Key to Principal Families of Diptera of Public Health Importance," separates 24 families of Diptera (two-winged insects including such common types as flies, mosquitoes, gnats, and midges).

Dr. Dodge, an entomologist with the Communicable Disease Center of the Public Health Service, is engaged in research work on flies.

This technical key, however, is not essential for the recognition of many common species of domestic flies.

In scientific practice, each kind of organism is given two names. For example, the common housefly is called "*Musca domestica*." *Musca* is the generic name and *domestica* the specific name. Generic names are always capitalized; specific names are not; both are italicized. Sometimes, when the generic name is mentioned previously, it is abbreviated to the first letter followed by a period, for example, *M. domestica*. In the accompanying pictorial key, some of the generic names are followed by "spp." An example is *Sarcophaga* spp. This means that more than one species occurs within the genus *Sarcophaga* but that the key does not separate the species. Often the name or an abbreviation of the name of the person who described the species is given after the specific name. For

*"Pollinose" refers to a whitish dusting of a surface caused by microscopic hairs.

example, the name of the common housefly may be followed by the name "Linnaeus," sometimes abbreviated Linn. or L.

A family constitutes a group of related genera. For example, the family "Muscidae" includes *Musca*, *Muscina*, *Ophyra*, *Stomoxys*, and related genera. Sometimes unrelated genera superficially resemble each other closely. On the other hand, members within one family may be quite diverse in general appearance. Thus, it is much simpler to recognize the housefly than to recognize its family characteristics. In fly control operations, the family name of a fly is of secondary importance; therefore, only the material in the "Pictorial Key to Common Domestic Flies in the U. S." is presented here.

Use of the Key

Identification keys are merely guides used to distinguish between closely related species. The most common type of key consists of a series of choices or "couplets," each containing two or more alternatives; each alternative refers the user to a succeeding couplet until the specimen under consideration is keyed or "run out" to a certain identity or name. In pictorial keys, most or all of the characteristics used in the couplets are illustrated.

In using the pictorial key shown, the general coloration of the body must first be determined. The housefly, for example, belongs in the gray-bodied group at the left. Three subdivisions of this group are based on the structure of the fourth wing vein. It can be observed even by the naked eye that this vein, which in many species ends behind the wing tip, is abruptly angled (not gradually curved) and ends before the wing tip, close to the end of the third wing vein. The presence of four dark stripes on the thorax and the usual yellowish coloration of the abdomen sets it apart from the various species of *Sarcophaga*.

Identifying another common fly, *Phaenicia sericata*, is not as simple. The uniformly greenish-colored body refers it to the group of species on the right side of the key. It will not be difficult to observe that the fourth vein is again abruptly angled or that the thorax is without obvious dark stripes, so it readily keys

NO'S 1-7 ARE THE "LONGITUDINAL WING VEINS" USUALLY REFERRED TO AS "VEINS"

past *Ophyra* and *Callitroga*. But its separation from the remaining genera and species is rather difficult. The whitish squamae (see fig. A of whole fly for location of this structure) and lack of a reddish spot on the side of the thorax (see arrow in key illustration) will put it with "*Phaenicia* and allies." The dorsal pollen of the abdomen gives it a duller color than the very bright, shining abdomen of most species of this group, but if the specimen is of the male sex, in which the pollen is less evident, it is useful to check the color of the squamae and the width of the interocular space (see illustration at this point in the key and fig. C). *Phaenicia sericata* can be separated from the remaining species, *Phaenicia pallescens*, by its usual greenish color and the other characteristics shown in the key.

As familiarity with the various flies increases there will be less and less need to refer to the key. The observer may even notice that some flies have prominent differences not mentioned in the key. For example, *Phaenicia* and allies

USUAL DIFFERENCE IN INTEROCULAR SPACE OF MALE AND FEMALE FLIES

C

are brighter colored than *Phormia* and *Protophormia*. In a key of this type, it is, of course, impossible to give all the outstanding characteristics. Some additional information on the various species follows. But it is advisable during the initial identification work to send representative determined specimens of all species to a specialist for confirmation.

Features of Common Species

Calliphora spp. and the allied species, *Al-drichina grahami*, a native of Asia now well established in California and Arizona, and *Eucal-liphora lilaea*, a common western species that is rare in the East, are quite easily recognized by the narrow, crescent-shaped, white margin of the lower squamal lobe. The identification of most species in this group is difficult, but two common species can be recognized as follows: *Calliphora vicina* (formerly called *erythro-cephala*) has cheeks which are mainly reddish, and it has a reddish anterior thoracic spiracle; *Calliphora vomitoria* has a "beard" of reddish-yellow hairs on the lower hind margin of the head. The species of the *Calliphora* complex are common in the Northern Hemisphere in the spring and fall. In the southern States they occur chiefly in the winter months. They breed primarily in dead animal matter.

Callitroga americana and *Callitroga macel-laria* range from Argentina to northern United States. They are very similar in general appearance but differ in habits. *C. macellaria* is a common fly over the greater portion of its range. It is readily attracted to traps and breeds in dead animal matter. *C. americana*, the "screw-worm" fly, is a primary parasite of mammals; its larvae occur in wounds and natural body orifices. Generally, it is larger in size than *C. macellaria* and the legs are usually nearly black. *Paralucilia wheeleri* is a western species which strongly resembles the two species of *Callitroga*, but it is distinguished from them by its dark brown squamae and longer palpi.

Cynomyopsis cadaverina is a common north-ern species allied to *Calliphora* and similar to that genus in habits and seasonal distribution. It is easily recognized through the nearly uni-form white squamae which contrast sharply with the dark body, and by the more strongly

shining abdomen which in both sexes is more pointed.

Fannia spp. are moderately small, grayish or brownish flies, sometimes marked with yellow. Certain species are black and shining, but they never approach the highly polished black of *Ophyra*. *Fannia canicularis* is commonly known as the "little housefly" and *Fannia sca-laris* as the "latrine fly." The sixth wing vein of *Fannia* is short and the seventh is sufficiently curved so that the two would, if continued, in-tersect before they reach the wing margin. *F. canicularis* and *F. scalaris* are nearly cosmo-politan in distribution, breeding in moist ma-terial of plant or animal origin.

Hylemya cilicrura and *Paregle cinerella* are two common examples of the Anthomyiinae, a subfamily characterized by the continuation of the sixth vein, though faintly, to the wing mar-gin, and by the presence of fine, erect hairs sub-apically on the under side of the scutellum. In *H. cilicrura* the female has a characteristic red-dish spot above the base of the antennae, and in the male the abdomen, viewed laterally, is quite flat. In *P. cinerella* the head usually is en-tirely black, and the male abdomen is not greatly flattened. Both species breed in vegetable matter, and they and allied species are some-times important pests of crops. They are widely distributed in the United States.

M. domestica, the "housefly," is easily recog-nized by the characteristics mentioned in the key, and there are few other American flies which might be confused with it. These are, primarily, *F. canicularis*, *Stomoxys calcitrans*, and *Muscina*. In other parts of the world there are many species of the genus *Musca*. *M. do-mestica* breeds in garbage, vegetable matter, or excrement of herbivorous animals, and is widely distributed throughout the world.

Muscina stabulans, the "false stablefly" and *Muscina assimilis* are widely distributed species, both probably originating in the Old World. They are well-marked species, somewhat larger than the housefly, and have a moderately curved fourth vein. They breed primarily in plant and animal wastes where their larvae may prey upon other fly larvae. Two allied, larger species are relatively new to North America, *Muscina pascuorum* and *Muscina pabulorum*. They are distinguished from *M. assimilis*, which they

otherwise resemble, by their larger size, the reddish palpi (not black), and by the strongly curved fourth vein, ending in or before the wing tip.

Ophyra aenescens and *Ophyra leucostoma* are easily recognized by the highly polished, shining black body. *O. aenescens* is bronzy-black with yellowish squamae, while *O. leucostoma* is bluish black with dark squamae. The difference in body color between these two species, though slight, is remarkably constant. Both species are widely distributed in the United States; they apparently prefer to breed in animal matter.

Phaenicia and the related species, *Lucilia illustris* and *Bufolucilia silvarum*, are quite difficult for the beginner to separate. *Phaenicia sericata*, the most common species, is variable in body color, ranging from its usual green to bluish, and occasional specimens have a reddish, "coppery" luster. Together with its closest ally, *Phaenicia pallescens*, it may be distinguished from the remaining species by a whitish pollinosity on the upper surface of the abdomen, especially in the females, and by the separation of the male eyes by a distance equal to or greater than one-tenth the width of the head. *P. pallescens* is a smaller species with body usually bronzy colored, sometimes with greenish luster but never coppery red. It is common in the southern States and is a close relative of *Phaenicia cuprina*, an important pest in Australia and Africa. Both *P. sericata* and *P. pallescens* are primarily urban species, being common in market districts and city dumps.

Phaenicia caeruleiviridis, *Phaenicia eximia*, *Lucilia illustris*, and *Bufolucilia silvarum* agree in that the abdomen is highly shining dorsally, and the eyes of the male are separated by a distance less than one-tenth the width of the head. These species all breed in dead animal matter, except possibly *Bufolucilia*, which is known to be a parasite of frogs and toads. *P. caeruleiviridis* and *P. eximia*, in contrast to *P. sericata* and *P. pallescens*, are mainly "rural" in their habits, seldom being encountered in city business districts or city dumps. However, they frequently may be taken in residential areas. *P. caeruleiviridis* is widespread east of the Rocky Mountains; *P. eximia* is a neotropical species which occurs in Texas and Louisi-

ana; *L. illustris* and *B. silvarum* are widely distributed in the northern and western States.

Phormia regina and *Protophormia terrae-novae* should be recognized without difficulty through their key characteristics. Both species breed in animal matter and occur primarily during the cooler months of spring and fall, or, in the southern limits of their range, in the winter. *P. regina* is deceptively called the "black blowfly," for its body is not black. Both species are of darker coloration than the various species of the *Phaenicia* complex. *P. regina* is usually dark green; *P. terrae-novae* is usually dark blue. Both species are widespread in the Northern Hemisphere. *P. regina* is the more common species, being absent or rare only in the southernmost parts of the United States.

Sarcophaga spp. includes a large group of genera and species of the family Sarcophagidae. These flies vary from three-sixteenths to more than 1 inch in length, and with few exceptions have three dark stripes dorsally on a grayish thorax. Some tropical species are bright yellow with black markings, or even metallic blue or green. The abdomen typically has a "checkered" pollinose pattern of changeable light and dark areas, with genital segments usually reddish but sometimes black. Female sarcophagids deposit living young.

Stomoxys calcitrans, variously called the "stablefly," or "dogfly," or "biting housefly," is a common and very widespread pest of livestock and will bite man freely. It breeds in excrement of herbivores, or in accumulations of vegetable wastes such as piles of grass clippings or seaweed. The elongated, stiff proboscis is characteristic of this species. In repose it projects for a considerable distance in front of the head. In size and general coloration, *Stomoxys* resembles the housefly but is further distinguished from that species by the moderately bent fourth wing vein and by the whitish pollinose spot on the front margin of the thorax.

Two other genera not represented in the key rate mention. *Pollenia rudis* frequently enters houses or attics in large numbers in the fall; for this reason it is called the "clusterfly." Although it keys to *Musca* and *Sarcophaga*, it differs from these flies in having a thorax that is not striped but is partly clothed with crinkly

yellowish hairs, particularly on the sides. The larvae of this species are parasitic on earthworms.

Scopeuma spp. are dung breeding flies which occasionally are common, and which are characterized by dense yellowish hairs and by the slender body. They would key out with *Hylemya*. They occur during the cool months of the year from the Arctic to the southern States.

At times certain other species of flies may appear to be common. It is impossible with limited space to deal with all species which may be encountered, but the species considered here constitute the bulk of the flies commonly associated with man in North America.

NOTE: The writer is extremely interested in the study of *Sarcophaga* flies, and will welcome material from any source. Many of the parasitic species are rarely taken in fly traps, but are more likely to be collected by rearing from host or by general collecting. Some known hosts are grasshoppers, mantids, snails, wasps, bees, caterpillars, spiders or their egg masses, and beetles. Many species breed in carrion or excre-

ment. If flies are obtained by rearing from larvae, the pupal shells should be pinned with the flies, and the host, in the case of parasitic species, should be preserved. Males of some rare species may be found sunning themselves upon rocks or barren ground on hilltops.

Regional Congenital Heart Program

The fourth regional program to help provide surgical and hospital care for children with congenital heart disease will be located at Johns Hopkins Hospital, Baltimore, where more than 1,200 "blue babies" have been operated on since 1945.

For the past 4 years, the Maryland State Department of Health has administered a small fund for congenital heart surgery for out-of-state children. Inclusion of the State in the regional program will extend and supplement this service to benefit children from the Middle Atlantic and Southern States. In special cases, children may be referred from other parts of the country if the care they need is available only at Johns Hopkins. Full geographic coverage for the country is planned upon completion of the regional heart center program.

Local funds, both public and private, in the State where the child resides, will be used for the major share of the costs. A special grant of the Children's Bureau, Federal Security Agency, may be used when such resources are not available. The grant will also provide convalescent sanatorium care and in-patient hospital care including special nursing and blood transfusions.

Regional programs previously approved are in New Haven, Conn., Chicago, Ill., and in San Francisco and Los Angeles, Calif.

Reported Tuberculosis Morbidity, January-June 1952

Provisional reports from the State health departments indicate there were approximately 56,000 cases of tuberculosis newly reported in the United States during the first 6 months of 1952. This is a slight decline from the numbers reported in the corresponding periods of 1950 and 1951. On the basis of these prelim-

inary data, it is estimated that some 6,000 fewer cases will be reported during the year 1952 than were reported in 1951.

A portion of the decline was due to the application of new case-reporting procedures in 1952. The new procedures limited the kinds of tuberculosis cases which should be reported,

SOURCE: Semiannual tuberculosis morbidity reports (provisional).

and in addition, provided that active and probably active cases should be counted separately from all other cases of tuberculosis.

In accordance with the recommendations of the State directors of tuberculosis control (*Public Health Reports*, October 5, 1951, pp. 1291-1294), State health departments report their new cases in two categories: group A—active and probably active cases; and group B—other reportable cases. This recommended reporting procedure was designed to achieve comparability of data on newly reported cases from State to State and to measure the problem better by identifying presumably infectious cases of tuberculosis needing treatment.

Of the 56,000 new cases reported from January through June 1952, 44,000 were designated as active or probably active cases—an estimated annual reporting rate of 57 per 100,000 population for the continental United States.

The tuberculosis morbidity rate continues to be high in spite of the rapid decline in mortality. This fact lends considerable importance to the numbers of cases newly reported each

This report was prepared by the Division of Chronic Disease and Tuberculosis, Public Health Service.

year as an index of the tuberculosis problem in the United States.

Shown in the accompanying table are total cases and group A (active and probably active) cases reported by each State and Territory. An improvement in comparability of data from State to State by the separate reporting of active and probably active cases is readily apparent. Total cases reported by some States (the only figures available in previous years) include only active and probably active cases, whereas totals reported by other States and Territories include cases of more limited clinical significance. As reporting improves, the annual reporting rate of active and probably active tuberculosis cases will no doubt become one of our best measures of the true tuberculosis problem in the various States and Territories.

1950 Census of Mental Patients

According to preliminary information, the number of patients in State and county mental hospitals increased in 1950. At the end of that year, about 600,000 were under supervision in 201 State and 112 county mental hospitals. This compares with more than 580,000 in the previous year. The average rate of all first admissions was 97.3 per 100,000 estimated civilian population.

Based on data compiled from an annual census by the National Institute of Mental Health, Public Health Service, these figures are reported in "Patients in Public Hospitals for the Prolonged Care of the Mentally Ill, 1950."

The National Institute of Mental Health points out that the increase may involve such factors other than an increase in the incidence or prevalence of mental illness as these: growth of the general population, increase in facilities for mental patients, earlier admission of patients through improved diagnostic methods, and hospitalization of patients who were previously untreated.

Industrial Sickness

Absenteeism

Rates for Specific Causes in 1951 and half of 1952

Men and Women 1951 The 1951 rate for sickness and nonindustrial injuries among men (131.2) is 12 percent above the 1950 rate (116.8) and 9 percent above the 10-year mean

(120.7). With the exception of the influenza and grippe rate, 1951 rates for specific causes do not differ notably from 1950 rates (see table 1). But 1951 rates for four causes are more than 30 percent above their 10-year means. Cancer is 57 percent above; other diseases of genitourinary system, 41 percent; infectious and parasitic diseases, 37 percent; and hernia, 31 percent. Frequency rates for these are all relatively low, varying from 0.7 for cancer for 1942-51 to 4.8 for other diseases of the genitourinary system for 1951.

The 1951 over-all rate among women (315.1) is 22 percent above the 1950 rate (258.4) and 29 percent above the 10-year mean (244.5). With only a few exceptions, the 1951 rates for specific causes are either approximate to or higher than the corresponding 1950 and 1942-51 rates. Note the increase in rates for influenza and grippe, pneumonia, neurasthenia and the like, and other diseases of genitourinary system.

1942-51

Among men, rates for nonindustrial injuries and the digestive group of diseases were highest in 1951, respectively, 27 and 20 percent above their 10-year means. Among women, 1951 showed the highest rates for all causes, for the respiratory group, and for the nonrespiratory-nondigestive group of diseases. In terms of

the 10-year means, the percentage excesses are 29, 35, and 30 percent, respectively.

Frequency by Duration

Frequency rates, shown in table 2, reveal that the rate for women is about twice the rate for men except for absences lasting more than 6 months. Table 2 is derived from the experience of 10 of the reporting organizations which pay benefits for 26 or 52 weeks.

Among both men and women, approximately four-fifths of the respiratory absences and one-half of the nonrespiratory absences lasted less than 1 month. Nonrespiratory diseases accounted for 80 percent of all absences lasting 57 days or longer (30.1 per 1,000 men, and 59.7 per 1,000 women). Twenty percent of the absences were caused by respiratory diseases and nonindustrial injuries combined. During 1951, 7 of every 1,000 men workers and 9 of every 1,000 women workers had an illness lasting more than 6 months. Ten men and 22 women of each 1,000 had an illness lasting from 3 to 6 months.

Days of Disability

Relatively small differences are found in the corresponding disability rates among men dur-

W. M. Gafafer, D.Sc., continues the quarterly and annual reports on industrial morbidity published in May and September 1952 and in earlier issues. Dr. Gafafer is in charge of the statistical services of the Division of Occupational Health, Bureau of State Services, Public Health Service.

¹ Data from 10 reporting organizations paying benefits for 26 or 52 weeks. ² Industrial injuries and venereal diseases are not included. ³ Digestive diseases, nonrespiratory-nondigestive diseases and ill-defined and unknown causes are included. Average number of persons: males, 55,853; females, 12,831.

ing 1951 and 1950 (table 3). Table 3 is based on the same population as table 2. In each year, nonrespiratory-nondigestive diseases accounted for one-half of the days of disability per man. Respiratory diseases and digestive diseases each accounted for about the same number of days of disability.

In 1951, women averaged 11.9 days of disability. Compare this with 9.8 in 1950. The excess is explained by an increase in both the frequency and the severity of nonrespiratory-nondigestive diseases (103.8 to 124.6 absences per 1,000, and 48.7 to 53.5 days per absence). If time lost from absences lasting less than 8 days were included, the number of disability days would have increased to approximately 13 per woman and 9 per man.

Men Jan-June 1952

Sickness absenteeism among men workers during the first half of 1952 (table 4) was about the same as in the corresponding 1951 period. In both years, the first quarter rates (170.9 and 168.8) are approximately 40 percent above the corresponding second quarter rates (120.9 and 121.5). Respiratory diseases account for the higher rates in the first quarter.

Note the similarity of the 1952 and 1951 second quarter rates for specific causes. Likewise, the 1952 first quarter rates for specific causes differ little from the 1951 corresponding rates with the exception of influenza and grippe.

NOTE: Data are derived from periodic reports of industrial sick benefit organizations and are limited to sickness and nonindustrial injuries causing absence from work for more than 1 week.

The 1950 annual report on men and women workers and an index of the reports from 1920-50 appeared in *Public Health Reports*, November 23, 1951, pp. 1550-1552.

World Health Day

The fifth annual observance of World Health Day will occur on April 7.

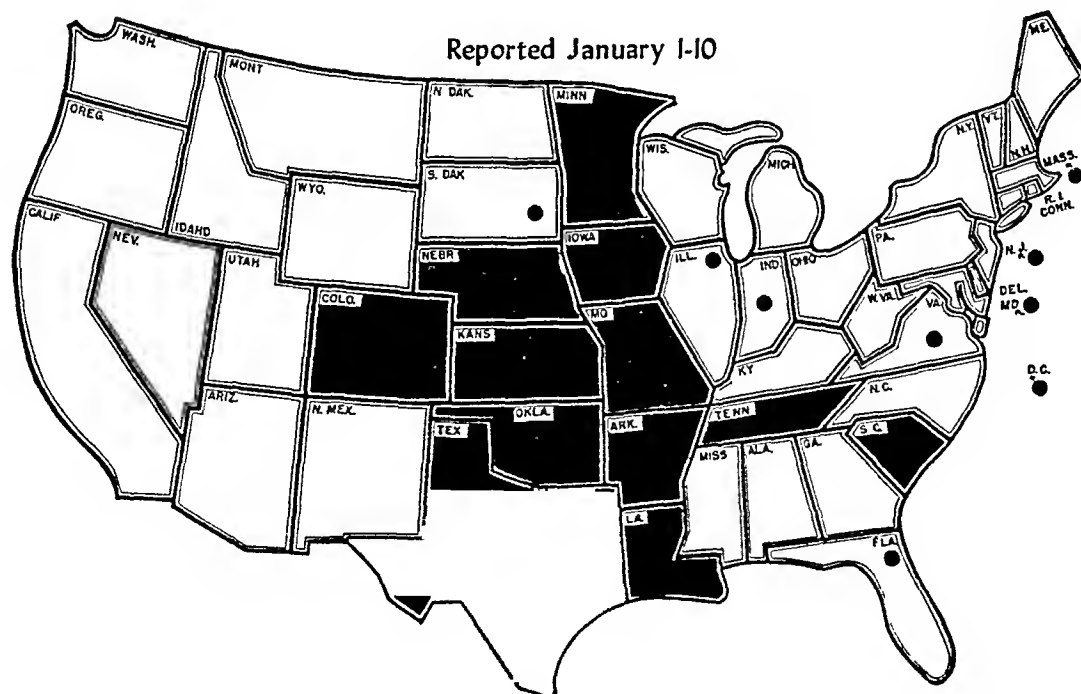

The theme for 1953 "Health is Wealth" is based on the economic value of health, which was emphasized in the discussions at the Fifth World Health Assembly, Geneva, Switzerland, in May 1952. The theme also is the main consideration in the World Health Organization monograph "The Cost of Sickness and the Price of Health," written by Dr. C.-E. A. Winslow, editor of the American Journal of Public Health.

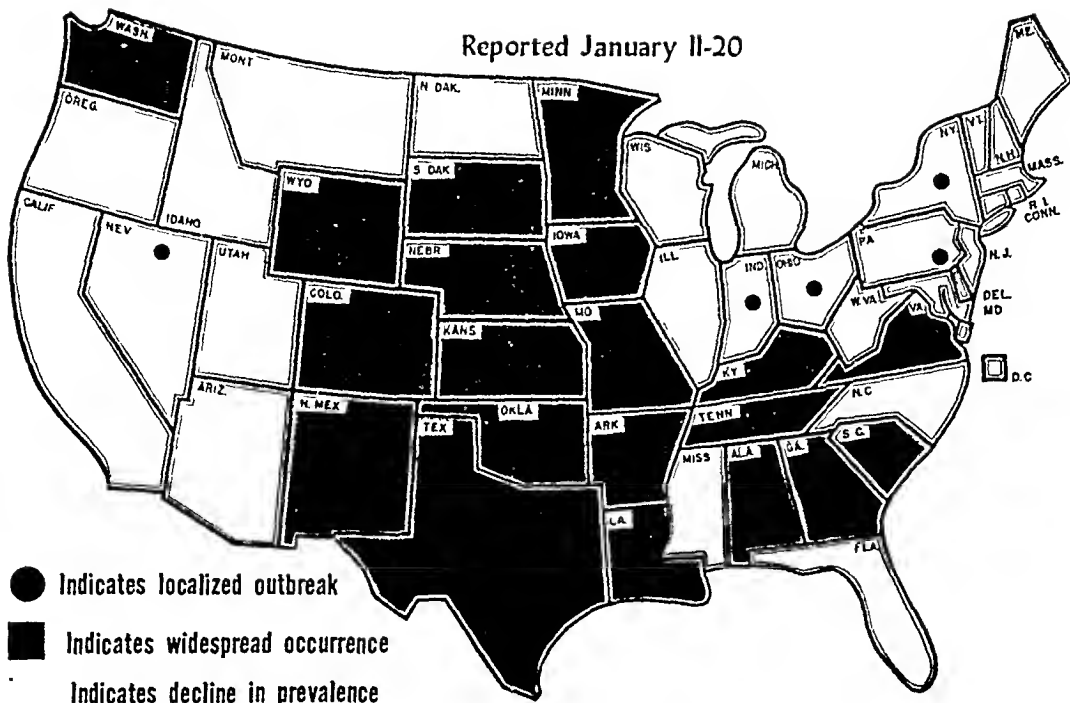

"Every step that can be taken toward lessening the burden of preventable diseases will not only diminish suffering and prolong human life; it will also increase productivity and promote prosperity," Dr. Winslow stated in the monograph.

Influenza Prevalence Trends

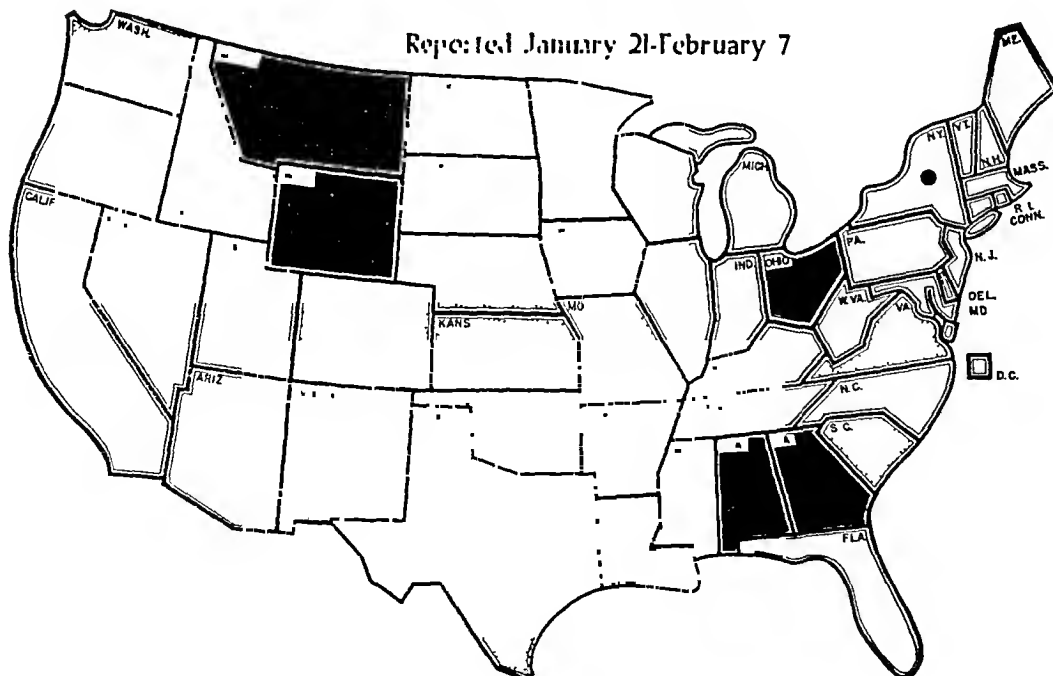

An A-prime type of influenza infection recently has been demonstrated in most parts of the country currently reporting respiratory disease outbreaks. At first infection was mild, with a low complication and a low death rate. Later reports indicated a somewhat higher mortality than usual. Localized outbreaks of respiratory disease began late in December—mainly in Colorado, Missouri, North Carolina, Illinois, Connecticut, and Oklahoma—among civilian, military, and institutional populations. A-prime infections in some of these groups were subsequently confirmed by serologic tests or isolation of the virus.

In the United States, 1952-53

During the first 10 days of January, respiratory disease was widespread in the central part of the country, and localized outbreaks occurred in the eastern part. Widespread outbreaks in some States and localized outbreaks in others continued during the next 10 days. The peak was reached late in January and early in February, though in the central part of the country the trend was already downwards. The true prevalence could not be determined. Some States made no reports, and others were not sufficiently informative to determine the extent of these infections, according to the National Office of Vital Statistics.

Proceedings of the Second Research Conference On Psychosurgery

The First Psychosurgery Conference was held in New York City in 1949 under the auspices of the National Institute of Mental Health, Public Health Service. Chaired by Dr. Fred A. Mettler of Columbia University, it devoted its attention to the criteria for the selection of psychotic patients for psychosurgery, such as topectomy, lobotomy, and gyrectomy.

The second conference, held in 1950, under Dr. Mettler's chairmanship, had as its theme the determination of the effects of psychosurgery and their measurement. The 2-day session covered such subjects as rating scales for psychotic patients, base-line data and psychiatric categories, evaluating the environmental situation of the mentally ill patient, and the study of affectivity, deterioration, regression, and creativity in patients following psychosurgery.

Among the points brought out by the discussants and presented in this publication was the need for a new approach to psychiatric categories, with the possibility of tying in some psychiatric subcategories to physiologic circumstances with resultant profit to psychiatric nomenclature. It was agreed that the scales presented were useful and well constructed, but "the psychiatrist himself still remains the most sensitive measuring instrument."

The viewpoint was presented that there is a "basic schizophrenia" underlying the schizophrenic psychosis; and that psychosurgery does not alter the basic disease process, but by relieving the stress of conflicting memories it may lessen the precipitating factors of the psychotic process.

Since depressed patients constitute another considerable group of patients for whom psychosurgery is

considered, affectivity was discussed. In this respect many problems were raised, for example, the relationship of anxiety to other affective responses; whether psychosurgery alters the affective states by inhibiting or facilitating activity and emotional expression; and whether it alters unconscious processes.

An analysis of creativity enumerated the four underlying abilities of that faculty as imagination, skill, problem-solving ability, and zeal. It was pointed out that the creative capacity is seldom up to the pre-operative level in psychosurgical patients, but by reducing anguish the operation may actually be followed by a rise in the level of creative ability.

Discussion also concerned the fact that all treatment procedures are aimed at the restoration of the patient to community life. A rating scale of family situations was presented as a measure of the degrees of stress in the situation to which the patient is exposed in the home. It was emphasized that for the patient who is returned to the community, the supportive attitude of the family is far more important than the physical environment. In like manner, the hospital adjustment of the patient is not necessarily a good index of his adjustment in a home situation which calls for self-direction.

Salaries of Local Public Health Workers April 1952

This study is the fourth in a series on salaries of selected public health workers begun in May 1948, in cooperation with the Association of State and Territorial Health Officers and the American Public Health Association. It contains information from 483 local health units, 303 local nonofficial health agencies, and

191 local boards of education. Data on public health nurses in the last two groups, usually published in supplements, were obtained and tabulated independently by the National Organization of Public Health Nursing and incorporated in this report for the first time.

The current study covers a wider range of professional classifications than was used in the three previous studies and includes for the first time data from health units serving populations of from 250,000 to 499,999 and 500,000 and over.

The data indicate that salaries of local public health workers in units serving areas of from 50,000 to 249,999 population advanced only moderately between April 1950 and April 1952. The greatest increase (27 percent) came to laboratory workers. Progressively smaller percentage increases were recorded for nurses, sanitary engineers, health officers, and sanitarians. Median salary intervals for those professional groups were (in dollars); health officers, 8400-8599; other public health physicians, 7000-7199; sanitary engineers, 5000-5199; supervising public health nurses, 4000-4099; professional laboratory workers, 3800-3999; sanitarians, 3200-3399; staff public health nurses, 3000-3099.

Effect of Fly Control on Diarrheal Disease In an Area of Moderate Morbidity

By DALE R. LINDSAY, Ph.D., WILLIAM H. STEWART, M.D.,
and JAMES WATT, M.D., Dr.P.H.

IN AN EARLIER study in Hidalgo County, Tex., flies were shown to be vectors of *Shigella* infections in an area of high diarrheal disease morbidity and mortality rates (1). The high rates and other features peculiar to that area were recognized as factors which might limit the applicability of this method of reducing such enteric infections in the more frequently encountered areas of low to moderate morbidity and negligible mortality. This paper presents the results of a study, very similar to the Texas study, made in such an area of low to moderate morbidity from diarrheal disease. The area selected is in southern Georgia. Its small communities are characteristic of the rural South in size, climate, and agricultural practices favorable to fly breeding and in community sanitation that allows flies ready access to human excrement.

Plan of Study

Fly control investigations were begun in Thomas County, Ga., in 1949. Of the six rural

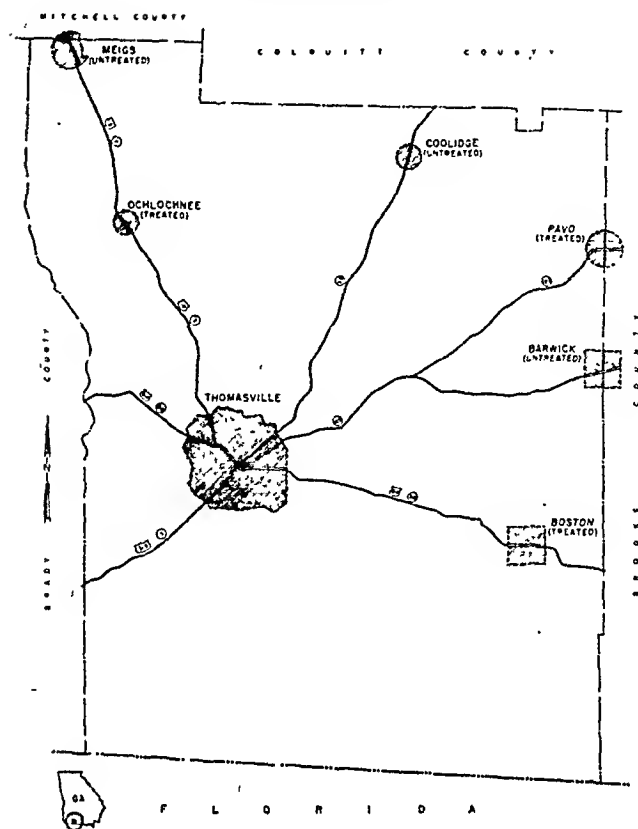

Dr. Lindsay is chief of the Thomasville Field Station of the Communicable Disease Center, Public Health Service, and Dr. Stewart is chief of the epidemiology unit of the station. Dr. Watt, formerly with the National Microbiological Institute, is now director of the National Heart Institute of the National Institutes of Health, Public Health Service. This paper is a third in a series of diarrheal disease control studies.

towns used in the study, Boston, Pavo, and Oehloehnee were selected for chemical treatment. Barwick, Coolidge, and Meigs, located between the treatment towns, were selected as untreated checks in an effort to equalize differences due to geographic location or agricultural practices (fig. 1).

Fly populations in the two groups of towns were measured by the Scudder fly grill method (2), and a minimum of the five highest grill counts per sample block was recorded. In the treated towns, all blocks were sampled weekly, to pinpoint areas in need of re-treatment. In untreated towns, representative blocks constituting only 10 to 20 percent of the total number of blocks were similarly sampled. The validity of this economy in sampling was established by comparable figures obtained when indexes of similar 10- to 20-percent samples, chosen by lot from the total samples of treated towns, were matched against the indexes of the total samples, as well as by supporting studies (3).

A town was re-treated when the average of the five high grill counts of flies exceeded three flies in any block. This lower re-treatment index, as compared with that used in the Texas study (1), was arbitrarily used in order to compensate for obvious differences in the two study areas. Blocks in the Georgia towns were much larger than those in the Texas towns, and numbers of fly attractants per block were higher. Thus larger populations of flies per index unit were represented. Comparison of the third high count averages in the Texas and Georgia areas indicated that the overall degree of fly

Figure 1. Location of study towns in Thomas County, Ga.

control achieved was comparable in the two areas. The third high count was used as an index, rather than the single high count, because it minimized vagaries due to single high concentrations of flies which sometimes were found.

Fly control in the treated towns was first accomplished by application of 5-percent DDT emulsion, using both space and residual spray methods. After 10 months of treatment, the high degree of DDT resistance which developed in the housefly (*Musca domestica* L.) population precluded further effective control with DDT. Dieldrin was therefore substituted in Pavo and in Boston. It was applied as a residual spray emulsion at rates of 50 mg. and 25 mg. of dieldrin per square foot of spray surface, respectively. Chlordan was substituted in Ochlochnee and was used as a residual spray emulsion applied at the rate of 100 mg. of chlordan per square foot of spray surface.

The effect of fly control on the prevalence rate of infection with *Shigella* and *Salmonella* organisms and on the rate of diarrheal disease

was measured by comparing the rates found in comparable population samples in the treated and untreated towns before, during, and after fly control. These rates were established by obtaining monthly rectal swab cultures from all children under 10 years of age in the samples, and monthly histories of diarrheal disease occurring in their families. Mortality rates from diarrheal disease were not used as a measure of the effect of fly control, because there were too few deaths for significant comparison.

The populations studied within the towns were in those neighborhoods having the highest proportion of children under 10 years of age. A disproportionate number of this age group was included since it has the greatest incidence of infection and disease due to *Shigella* organisms. The population figures for 1950 in the treated and untreated towns and in the samples selected in these groups of towns are given in table 1. The total populations of treated towns and untreated towns were approximately equal. The sample population included slightly less than one-half of the total population in each group of towns.

Results of Fly Control

Effects of the chemical control operations upon all common species of flies, considered as a group, are shown in figure 2. A 3-week moving average of the median or third high grill counts for all survey blocks is used as an index of the fly populations observed in the two groups of towns. Weekly fly counts were made for approximately 3 months before control op-

Figure 2. Effect of chemical control operations on all species of flies (3-week moving average of third high fly count).

erations were begun, and, except for the first 3 weeks, index trends for both groups were very close. Control operations for 1949 began on July 18 in Pavo, on August 1 in Ochlochnee, and on August 10 in Boston. The intervals between these dates were taken up with the original treatment of the new town and re-treatment, as needed, in the town or towns previously treated. The fly population index of the treated group declined as each of the towns came under operational control. Normal seasonal increases in the fly population in the untreated towns continued into November 1949,

when cool weather curbed fly activity and breeding.

Warming weather in January and February 1950 resulted in rising population indexes in both groups of towns during January and forced intensification of operational control in the treated towns during February. The results of this control intensification can be seen clearly in comparing index lines for February in figure 2. Cool weather in March and early April held both fly breeding and activity in check and did not permit the taking of reliable population indexes through March. During the first 2 weeks of May the indexes for both groups rose sharply in spite of heavy reapplications of DDT in the treated towns.

Concurrent field observations and laboratory tests showed that houseflies (*M. domestica*) had become highly resistant to DDT, and with the rising mean temperature the ineffectiveness of DDT increased in accordance with principles established by Lindquist and associates (4, 5). This trend toward housefly resistance to DDT was established by laboratory tests of wild flies taken from the treated towns before it was reflected by increased grill counts in the field. As a result of these laboratory tests, conducted according to a standardized procedure reported by Lindsay and Haines (6), substitute insecticides for DDT were on hand when needed. These insecticides, dieldrin and chlordan, were applied as described in the plan of study between the dates of May 16-26. Good control was maintained in the treated towns until late August 1950, compared with an increased fly

Figure 3. Number of *Musca domestica* compared with other flies in treated towns of Ochlochnee, Pavo, and Boston, Ga. (3-week moving average of third high fly count).

population index for the untreated towns during July and August.

Throughout June and July 1950, the degree of fly control achieved by using dieldrin and chlordan was so nearly perfect that it was difficult to find individual flies, and concentrations of two or more flies were only rarely encountered. In late August, scarcely 12 weeks after the initial application of dieldrin and chlordan, it became evident from laboratory tests that housefly populations had gained immunity to these insecticides, as well as to DDT. Large populations were not found, as evidenced by the low fly index for the treated towns throughout August, but laboratory tests on small representative collections of these populations revealed a high degree of resistance to dieldrin and chlordan. These tests showed that dieldrin and chlordan selected houseflies with the same resistance factors. Chlordan resistance was found where only dieldrin had been used and dieldrin resistance where only chlordan had been used. After a high degree of dieldrin or chlordan resistance had been attained in field populations of houseflies, no dead or dying flies could be found as a result of the reapplications of these insecticides, and laboratory tests of wild flies showed no appreciable differences in the mortality of flies subjected to heavy residuals of dieldrin and of flies in the untreated checks.

Although DDT used against resistant houseflies would not produce satisfactory fly control, both dead and dying flies were easily found in the field following reapplication of DDT dur-

ing October and November 1950, and the mortality of wild flies in laboratory tests against DDT residuals was significantly higher than in the untreated checks. Fly control by various field combinations of insecticides and of application methods was then attempted, and the decline shown in the treated towns' index during November was due mainly to reapplication of DDT sprays, probably enhanced by cool weather (4, 5).

As previously found in the Texas study, all marked failures in fly control operations were due to inability to control the common housefly. This fact is illustrated in figures 3 and 4, presented on scales identical to those in figure 2. The major role played by the housefly in developing resistance to insecticides is quite apparent in figure 3. It was the only species that increased significantly during the use of the insecticides.

In the three untreated towns all index points above 10 for species other than the housefly were due to seasonal increases in the single subtropical species *Sarcophagula occidua* Fabr. of the family Sarcophagidae (fig. 4). This species breeds abundantly in animal excrement and reaches its peak of breeding in late fall. An abundance of favorable media in the rural towns under study permitted large-scale breeding.

When considered in terms of habits and control difficulties, houseflies appear to be the primary species concerned as *Shigella* vectors. Results of ecological studies by Haines (7) of the

Figure 4. Number of *Musca domestica* compared with other flies in untreated towns of Meigs, Coolidge, and Barwick, Ga. (3-week moving average of third high fly count).

commonly occurring flies showed that houseflies were highly adaptable in using a wide variety of naturally occurring refuse as breeding media. Refuse was classified by source and nature into approximately 20 categories, and investigation revealed that houseflies bred in all categories, sometimes in numbers far smaller than the species most favored, but nevertheless in significant quantities. Since by qualitative standards the types of media most favorable to housefly breeding, such as animal excrement and bedding in stables, were also highest in frequency of occurrence and in volume in the study area, the greater relative abundance of houseflies at all seasons, as compared to that of other species, is to be expected.

Diarrheal Disease

Data on the prevalence of *Shigella* infections in children under 10 years of age in treated and untreated towns are grouped in two ways: by quarters of years and by periods covered before, during, and after fly control (table 2). At the beginning of the study, prevalence rates in the two groups of towns approximated one another. With the beginning of fly control operations in July 1949, the prevalence rate in the treated towns fell, and remained low, whereas the rate in the untreated towns continued high. This relationship remained during the period of good fly control from September 1949 to late August 1950. When effective fly control was lost, after August 1950, the percentage of

Shigella infections in treated towns rose until, in October 1950, it exceeded the rate in untreated towns. For the next 12 months, rates in the treated and untreated towns remained on a level similar to that before fly control started. The percentage of *Shigella* infections before, during, and after fly control is shown in figure 5.

The number of isolations of *Salmonella* organisms during this study was quite small. However, there were just as many isolations made in treated towns as in untreated towns during effective fly control. This lends weight to the previous report (1) that fly control did not influence the spread of these organisms in the same way that it did the *Shigella* group.

The crude and standardized attack rates per 1,000 a year for reported diarrhea in children under 10 years of age were almost identical in the treated and untreated towns for the 8 months before fly control operations began (table 3). During the year fly control was maintained, the rate of reported diarrheal disease was appreciably lower in the treated towns, but showed little change in the untreated towns. After fly control was lost, the rate of diarrheal disease in treated towns rose to slightly below that in untreated towns. The significant change in the attack rate of diarrheal disease in treated towns during the fly control period is shown in figure 6.

Reversal of the treated and untreated towns in order to duplicate the effect of fly control on diarrheal disease was impracticable because of the relatively high insecticidal resistance in

Figure 5. Prevalence of *Shigella* infections in children under 10 years of age before, during, and after fly control.

Figure 6. Standardized attack rates for diarrhea in children under 10 years of age before, during, and after fly control.

the previously untreated towns. This resistance, detected by laboratory tests, could have resulted from widespread individual use of household and agricultural chemical insecticides.

Table 3. Crude and standardized attack rates for reported diarrhea in children under 10 years of age before, during, and after fly control

Period	Treated					Untreated					Probability "p"
	Person-months observed	Cases	Crude rate ¹	Expected cases	Standard rate ¹	Person-months observed	Cases	Crude rate ¹	Expected cases	Standard rate ¹	
Before fly control: Jan. 1949 through Aug. 1949-----	2, 258	39	207	44. 2	235	2, 660	46	208	46. 8	211	0. 99
During fly control: Sept. 1949 through Aug. 1950----	3, 084	29	113	34. 0	132	3, 511	57	195	60. 8	208	. 015
After fly control: Sept. 1950 through Jan. 1951-----	790	17	258	21. 3	324	896	25	335	25. 6	355	. 40

¹ Per 1,000 a year.

The fact that the period of effective fly control was the only time during the 32 months of this study that the prevalence rate of *Shigella* infection was significantly lower in the treated towns than in the untreated towns is convincing evidence that flies were vectors of *Shigella* organisms. The lowering of the attack rate for diarrheal disease during the period of fly control indicates that a significant portion of this diarrhea resulted from infection with *Shigella* organisms, and again points out the importance of *Shigella* infections as a cause of diarrheal disease.

Summary

Results of this study demonstrated that during effective fly control in an area of moderate diarrheal disease morbidity, the prevalence rate of *Shigella* infections and the morbidity rate from diarrheal disease were significantly lowered.

Chemical insecticides of the residual type were used for control of adult flies. The development of housefly (*M. domestica*) resistance to the DDT initially used resulted in its ineffectualness in maintaining fly control after 10 months. The dieldrin and chlordan sprays

substituted for DDT resulted in excellent fly control for about 3 months. After that period these insecticides became even less effective than DDT.

Vending Stand Program Aids Blind

More than 1,700 blind vending stand operators and employees earned over \$3.6 million during 1952, according to figures released by the Office of Vocational Rehabilitation, U. S. Department of Health, Education, and Welfare. These are the highest net earnings ever recorded by the blind men and women who operate vending stands under the guidance of the Nation's State-Federal program for rehabilitating disabled civilians. Gross sales exceeded \$18.6 million.

The vending stand program provided in 1952 self-sustaining work for 1,513 blind operators, 196 blind assistants, and 412 other workers employed by the operators.

Five hundred and fifty-eight of the 1,479 vending stands are operated under the program in Federal buildings. The others are on private or non-Federal public premises. The investment in equipment and merchandise totals more than \$2.3 million.

*The Great Central Valley
of California*

OUTBREAK in California

By WILTON L. HALVERSON, M.D., Dr.P.H., WILLIAM ALLEN LONGSHORE, Jr., M.D., M.P.H.,
and RICHARD F. PETERS, B.S.

DURING THE PAST summer California experienced the highest incidence of infectious encephalitis thus far recorded in this State. A total of 729 human cases was reported from 37 counties during the June to October encephalitis season. Ninety-four percent (689) of the cases occurred in the 20 Central Valley counties. Over half of the cases were confirmed by laboratory tests. Fifty-one deaths were listed as having resulted from this disease. Four hundred cases of encephalitis in horses were reported during the season.

The present account is concerned primarily with the emergency plan worked out to cope with the 1952 outbreak of infectious encephalitis caused by one or the other of two viral

agents, namely, viruses of western equine encephalomyelitis and of St. Louis encephalitis. Special studies were undertaken along with emergency control activities to gain as much additional epidemiological information as possible regarding infectious encephalitis, which is endemic in various parts of the country and which becomes epidemic under conditions which are not well understood.

California History, 1938-51

Infection of man with western equine encephalomyelitis virus in California was first suggested by pathological specimens in 1932 but was not confirmed by isolation of the virus until 1938. Prior to that time the virus was considered to produce a disease only in horses. Human infection with the St. Louis virus was first recognized in California in 1939. In the years following the recognition that these agents could cause infection in man, human illness attributable to these viruses in California has been found to be relatively common in the Central Valley areas (see map). Since 1938, certain observations have been recorded concerning the epidemiological and clinical aspects of enceph-

Dr. Halverson is the director of the California State Department of Public Health. He has recently been to South America as a consultant on public health affairs. Dr. Longshore is assistant chief, bureau of acute communicable diseases, and Mr. Peters is chief of the bureau of vector control of the department. Another member of the staff of the department, Arthur C. Smith, took the photographs used in this article.

alitis caused by these two specific agents as they have occurred in California.

There has been a wide variation from year to year in the number of cases of infectious encephalitis reported. Incidence of the disease in California was highest in 1945 and 1950, when

Human cases of acute infectious encephalitis reported in California, 1938-52.

320 and 357 human cases, respectively, were reported. The lowest number of cases reported was 71 in 1948. Laboratory studies have been carried out on a good percentage of these cases, particularly since 1945, when the State viral and rickettsial disease laboratory began to perform serologic tests as a routine procedure.

Cases of infectious encephalitis have been reported from 46 of the 58 counties in California. The preponderance of cases, however, has been reported from the Central Valley areas (see map), with the largest number in Kern, Fresno, San Joaquin, and Tulare Counties. Moreover, it is considered significant that the laboratory confirmed human cases of western equine encephalomyelitis and St. Louis encephalitis have been confined almost exclusively to the Central and Imperial Valleys, leaving the coastal areas relatively unaffected.

Laboratory confirmed cases have been reported from only 23 counties of the State, and

distribution within the State is limited essentially to the hot, irrigated agricultural sections of the Central and Imperial Valleys. This geographic distribution appears to reflect to some degree the distribution and density pattern of the principal mosquito vector, *Culex tarsalis*. Also, laboratory confirmed cases have occurred only during the months of June through October.

Experience gained over a period of some 12 years, with the seasonal occurrence of endemic arthropod-borne encephalitides in the Central and Imperial Valleys of California, proved valuable in carrying out the emergency encephalitis program in 1952. The following factors also contributed in an important way to the success of the emergency program:

1. The excellent diagnostic facilities provided by the California State Health Department's viral and rickettsial disease laboratory.

Human cases of infectious encephalitis reported in California, by month of onset, 1952 and 1950.

*Total for 1950 includes 6 cases with date of onset not stated.

2. The alertness of the private practicing physician to this particular illness.

3. The awareness of the problem on the part of local health departments.

4. The intensified activity of the mosquito abatement districts.

5. The good working relationships between

the State health department, local health departments, and mosquito abatement districts.

Mosquito-Breeding Factors

During the winter of 1951-52 one of the heaviest snow packs ever recorded was deposited upon the mountain ranges of California, and rainfall throughout the State was extraordinarily heavy. Winter and springtime average temperatures were relatively moderate, with only a few short periods of critically low temperature to work adversely upon the overwintering mosquito population. These conditions apparently proved optimum for the rapid development and biotic potential of the *C. tarsalis* population during the early spring. Not only was the distribution of this mosquito more general in 1952, but extensive water in the river-bottom lands and various low flooded areas were observed to produce the insect in extraordinary numbers. As is characteristic in California, mosquito population peaks were first reached in the lower San Joaquin Valley and progressed northward through the spring and summer.

Within the 21 mosquito abatement districts comprising the area under organized mosquito control in the Central Valley, intensive control operations were directed against *C. tarsalis*. The breadth of the breeding area, however, exceeded the physical resources available and it was not possible to prevent emergence of a large portion of the adult mosquitoes.

The resistance of *C. tarsalis* to DDT and other chlorinated hydrocarbon insecticides, which had been demonstrated conclusively the previous season, appears to have played a significant part in reducing the effectiveness of chemical control measures used.

Mild spring climatic conditions, aside from greatly favoring the reproduction of *C. tarsalis*, apparently increased its longevity. Moreover, the 1952 flights of this mosquito are believed to have greatly exceeded the range earlier attributed to it. Earlier scientific measurement of the flight pattern of *C. tarsalis* had shown it capable of flights of approximately 2 miles; indications this year were that it flew 5 to 10 miles or more.

Equine encephalomyelitis cases reported in California, by month, 1947, 1950, and 1952.

By June most of the mosquito abatement districts in the San Joaquin Valley had felt the impact of the *C. tarsalis* problem and every emergency measure available was put to work against this mosquito. A further factor of significance was that the production of this mosquito in such large numbers led to its invading homes and biting man in a manner not previously observed. Ordinarily, this mosquito seeks and prefers the blood of either domestic or wild fowl.

By July the important aquatic sources of *C. tarsalis* had largely changed from characteristic natural sources to places incidental to the use of irrigation water in agriculture. This change, and the apparently decreasing adult mosquito populations, gave promise that *C. tarsalis* populations would also subside. In addition, the Central Valley experienced several days of maximum temperatures exceeding 100° F., a condition unfavorable to adult mosquito survival. This provided additional hope that the mosquito population would decrease to a level approaching normal for that time of the year. However, such optimism proved to have been ill-advised.

Beginning of the Outbreak

Since 1943 it had been the practice of the Hooper Foundation of the University of California and the State health department to assign medical personnel to the Kern General Hospital at Bakersfield, during the summer months, to observe all cases admitted to the communicable disease ward. Histories and adequate diagnostic specimens, with thought for the encephalitides, were taken routinely. When a visit was made to the Kern County area in early July for the purpose of placing a student, an unusual increase in the number of encephalitis cases was noted. Some 25 suspect admissions to the Kern General Hospital during June had been recorded.

As July progressed, an increased number of cases of encephalitis was noted from the lower San Joaquin Valley area, where the disease ordinarily makes its first appearance, and two human cases were reported by the health officer of Madera County. Also, the virus laboratory was beginning to receive increased numbers of diagnostic specimens from patients suspected of having encephalitis.

Initial State Planning

In view of these developments, a meeting was held on July 14, 1952, in the office of the director of public health to review the situation with the mosquito abatement officials and the advisory committee of the bureau of vector control. Following this conference a press release was issued stating that a potential epidemic of encephalitis was at hand. A previous telephone conference had been held with the 20 health officers of the endemic areas explaining the plan of action and pointing out that a news release was to be made. Advance copies of the State release were sent to the local health officers so that simultaneous statements could be made in the local press. A second meeting with the vector control advisory committee was held on July 28, 1952, to which all of the health officers of the counties in the endemic areas of the State were invited.

Out of this and a later series of meetings came plans for an intensified program directed specifically toward the suppression of the *C. tarsalis*. This program, "Operation *Culex tarsalis*,"

was created to augment resources of the 21 existing mosquito abatement districts in the Central Valley and to assist local areas outside these districts in planning emergency control operations.

Administrative Problems

Upon declaration of the emergency, the director of the State department of public health designated the chief of the division of environmental sanitation to coordinate the overall program. The bureau of acute communicable diseases was assigned full responsibility for conducting the epidemiology, and the bureau of vector control was likewise charged with accomplishing the necessary mosquito control. The division of administration provided direct assistance in facilitating the procurement and delivery of needed equipment, materials, and supplies. The viral and rickettsial disease laboratory organized its facilities to perform all the necessary laboratory functions.

At the same time epidemiological followup of cases of encephalitis occurring in the Valley areas was intensified. All indications pointed to the likelihood that the number of cases would increase. It was forecast at that time that there would be between 500 and 700 cases for the disease year. Close followup was thought to be desirable to obtain complete epidemiological data on all cases of central nervous system disease with fever admitted to the hospitals in the 20 counties involved. It was thus necessary to arrange for increased activity on the part of the virus laboratory to process the additional specimens which would be secured through the intensified diagnostic effort.

State and Federal Aid

As State and local agencies moved into action, the Governor, on August 1, 1952, made \$250,000 in emergency State funds available. This grant of funds enabled the State health department to provide the financial assistance necessary to marshal materials and manpower for the intensified operation. Many of the Central Valley counties also made funds available for the control program.

At the request of the State director of public

health, the Federal Public Health Service dispatched to California, from stations in various parts of the country, 22 technical personnel from its epidemic intelligence service and other branches to aid both the mosquito control work and epidemiological investigations.

Knowing that professional and technical assistance was forthcoming, the emergency program was planned so that the project would operate in two major fields: a field epidemiological program under the guidance and supervision of the bureau of acute communicable diseases, and an emergency mosquito control program to be carried out under the guidance and supervision of the bureau of vector control.

Epidemiology Program

The emergency epidemiological planning embraced two areas: central office activities, which included the modification of reporting procedures and the issuing of laboratory diagnostic notifications, and emergency field epidemiology, which made use of the services of personnel from the Federal Public Health Service.

The virus laboratory reported to the bureau of acute communicable diseases the results of blood tests and the receipt of first bloods (the first blood specimen of paired series required for diagnosis) submitted for diagnostic encephalitis studies. This information, together with the information obtained in the routine processing of morbidity cards sent in by local health departments, was used to alert the field teams to possible diagnostic cases so that master lists of suspected cases could be prepared for the field personnel.

The field epidemiology program was set up on the basis of four zones, covering the endemic areas of the State. The epidemiology teams—2 physicians and 1 veterinarian—had headquarters in the cities of Sacramento, Stockton, Fresno, and Bakersfield. Each operated through the local health departments and their respective county hospitals, which receive the majority of cases. The epidemiology teams also covered the counties adjacent to headquarters. The zones and their headquarters were:

Zone 1. Headquarters at Sacramento—including the counties of Sutter, Yuba, Yolo, Placer, Sacramento, and Butte.

PLANNING AND ADMINISTRATION

Top: Discussing distribution of encephalitis cases with the San Joaquin County health officer. Center: Planning residual spray program in Stockton. Bottom: Emergency encephalitis control staff meets at Fresno.

EPIDEMIOLOGY

Above: An interview with the family of a patient. Top right: Interviewing an encephalitis patient in the Stockton County Hospital. Lower right: Taking a blood sample from a patient's father.

Zone 2. Headquarters at Stockton—including the counties of San Joaquin, Stanislaus, and Merced.

Zone 3. Headquarters at Fresno—including the counties of Madera, Fresno, Kings, and Tulare.

Zone 4. Headquarters at Bakersfield—including the county of Kern.

The personnel from the Public Health Service's Communicable Disease Center, augmented by members of the State staff, were detailed to the zones. Two physicians were assigned to each zone and a veterinarian to each two zones. The majority of these emergency assignments were for 1 month. This necessitated replacements from time to time due to commitments of the assignees to return to their previous stations. While these replacements could not be avoided, the lack of continuity in the conduct of the epidemiological work was marked, and there was continuing need for orientation of new assignees.

The objective of the field epidemiological studies was to obtain laboratory confirmation

of cases of encephalitis and to secure as early and completely as possible the detailed epidemiological information concerning the disease in both humans and horses. The epidemiology teams were so placed that they would be able to undertake studies immediately upon receipt in the field of reports of suspected cases. Briefly, the field operations included these three elements:

Human Cases. In the four epidemiology zones, all known central nervous system encephalitis cases with fever were followed closely. Attempt was made to collect blood from these individuals in the acute and in the convalescent stages of the disease and to obtain complete epidemiological data. Autopsy specimens were secured on fatal cases whenever possible. The great majority of the blood specimens were taken by the hospital staffs, but collection of blood from discharged convalescent patients was the responsibility of the epidemiology teams. Specimens were tested in

the State laboratory by complement fixation or animal neutralization.

Two auxiliary studies were undertaken in special areas. In zones 1 and 2 an associate survey was attempted in which all household associates of known cases were bled once to determine their immunity status. The second special program, carried out in the Fresno County and Stanislaus County Hospitals, included a serologic survey of all febrile hospital admissions, in an attempt to broaden the clinical basis for the diagnosis of encephalitis. When possible, blood specimens were taken both during the acute and convalescent stages of the disease on all febrile admissions to the hospital, regardless of admission diagnosis.

Horse Cases. The State department of agriculture furnished reports on all known cases in horses. Veterinarians on the epidemiology teams collected and submitted to the virus laboratory as many paired bloods as could be obtained from clinical cases in horses and, when possible, secured post-mortem brain specimens for virus recovery and identification.

Special Studies in Outlying Areas. Epidemiological studies were made in selected areas outside of the Central Valley where cases in humans or a large number of cases in horses had been reported. The studies were particularly concerned with the fringe areas outside of the valley counties in order to determine the geographic distribution of the disease. Verification of *C. tarsalis* prevalence was sought and, when possible, mosquito pools were collected for virus recovery studies. These special studies were performed by teams of physicians, veterinarians, and entomologists operating from headquarters on special assignment.

Mosquito Control Program

With *C. tarsalis* mosquitoes already numerous, practical decisions had to be made with respect to control measures which would reduce the hazard to the majority of the residents of the valley. This logically resulted in a plan which gave priority consideration to towns and cities and adjacent suburban areas. Any effort to cover the entire valley would have diluted the control resources to such an extent that the

VECTOR CONTROL OPERATIONS

Top: Spraying a cotton field for *Culex tarsalis* larvae near Porterville. **Center:** Laying down an aerosol fog at a fairgrounds near Colusa. **Bottom:** Larvaciding at home of an encephalitis patient near Stockton.

prospect for accomplishment would have been generally negated.

Since the 21 mosquito abatement districts in the valley had been conducting expanded activities against *C. tarsalis* for a month or more, their principal need was for additional funds with which to expand and further intensify their emergency activities. The uncontrolled

ENTOMOLOGICAL AND VIRUS RECOVERY OPERATIONS

portion of the valley, however, required a complete plan to develop local participation and to provide technical personnel who could direct operations and get control work under way immediately. The same general plan of controlling mosquitoes was recommended for both the mosquito abatement districts and the uncontrolled territory. This consisted of methods designed to reduce an existing adult mosquito population and, if possible, to maintain it at a low level for the period of the emergency.

Essentially, the mosquito control program had three parts: (a) space (aerosol) spraying at frequent intervals; (b) barrier spraying of a quarter mile band on the periphery of each city and town; and (c) intensive larviciding or correction of mosquito sources within cities and towns and outward to a radius of 2 miles.

Control teams were organized combining Communicable Disease Center personnel with members of the staff of the bureau of vector control. Six such teams were established and dispatched to the six major uncontrolled areas of the Sacramento and San Joaquin Valleys, which include all or parts of Tehama, Glenn, Colusa, Placer, San Joaquin, Fresno, Tulare, and Kings Counties. Each team consisted of an engineer, an entomologist, and at least one vector control officer.

Since State funds were largely consumed in the purchase of spray equipment and insecticides, the teams were obliged to stimulate local participation in each individual mosquito control effort. Wherever local health departments were available they were used as the nucleus for conducting and encouraging the mosquito control operations. In some localities the office of the agricultural commissioner served this function in lieu of the health department. As a whole, the response by local officials to the emergency was very good. Local funds were made available in many localities to employ operators. In some cases local workers were loaned to the cause. Each team was provided 1 aerosol machine, 8 exhaust aerosol generators for installation on local vehicles, and 33 cylindrical-type hand sprayers, plus all of the spray equipment which could be recruited in each zone. DDT and diesel oil were provided

wherever needed. Airspray operations were conducted in certain areas where this method of operation was indicated.

The bureau of sanitary engineering assisted by inspecting and obtaining rapid treatment or correction of mosquito sources associated with community sewage disposal lands. The bureau of health education provided two health educators to assist the local health departments and other agencies participating in the emergency program and otherwise to facilitate the securing of local support and participation. A leaflet, "Kill Mosquitoes, Protect Your Family From Encephalitis," which contained helpful suggestions to the individual householder, was distributed liberally by local health departments and mosquito abatement districts throughout the Central Valley.

Entomologists, in addition to sampling mosquito prevalence and guiding control operations, collected and submitted over 1,100 pools of mosquitoes to the viral and rickettsial disease laboratory for virus recovery studies.

A Note in Summary

This brief account outlines the organization and plan used in conducting the emergency epidemiology and mosquito control programs in California during the summer of 1952. As is characteristic of any emergency, administrative problems were encountered in the course of this antientcephalitis effort. There was, for example, the lack of a previously conceived specific plan, the problem of how to utilize most effectively the personnel unfamiliar with California conditions, the matter of forced rotation of personnel, communications, fiscal arrangements for participating personnel, and procurement lag. These problems will be covered in detail in a later report.

At this writing it is premature to attempt to evaluate the epidemiology of the outbreak or to comment on the effect of the mosquito control effort in arresting or altering the course of events. Upon completion of the analysis of the multitudinous data collected on both aspects of the subject, such conclusions will be duly reported.

Time Study of Public Health Activities In Mississippi

By J. A. MILNE, M.D., M.P.H., MARGARET E. RICE, M.S., JOHN B. HOZIER, M.D., M.P.H., and
GRACE B. TARANTO, B.A.

OF IMMENSE potential value to the public health administrator in planning and executing an adequate public health program is the knowledge of the relative amount of time and effort devoted to each of the categories of public health service. Selection of the best means for determining this relative emphasis among program activities, however, presents a problem of some import. There are possibly infinite varieties of ways for the determination of emphasis among activities, each having certain merits when applied to a particular situation. The time study is a basic approach to the measurement of effort expended when dealing with a multiplicity of activities.

The Setting of the Problem

Public health needs have changed dramatically in the last 10 years. Concepts of a good public health program, and the services it should include, likewise have changed. A program of 10 years ago did not provide many of the services which today are considered necessary if recognized needs are to be met. Even today, it has not been possible to supply

the minimum services essential in many communities.

The public health administrator not only must accept today's challenge but also must foresee and plan for future needs. It is as much his responsibility to work now for the expansion required to meet future needs promptly and efficiently as it is to provide currently the best possible service with the money and personnel at his disposal.

With pressures for more services in new and broader areas constantly building up around the public health worker, the evaluation of day-to-day operations frequently has been neglected. It is readily apparent that these same pressures, which urge more, better, and quicker services, make it doubly important that only essential and productive activities be conducted.

A sound, objective evaluation of a public health program is difficult in many instances. Programs have evolved so rapidly that the definition and the development of adequate measures of progress have not kept pace.

The Need for Bench Marks

To determine progress in any sphere, it is first necessary to know just what is being done at present. In the health department, information concerning activities and services is furnished in a variety of ways. There are annual program reports, local activity reports, special project reports, financial and statistical reports, and others. Each ordinarily portrays or emphasizes only a segment of the program.

Dr. Milne is director of the division of county health work, Mississippi State Board of Health, Jackson, and Miss Rice is supervisor of the statistical service for the board. Dr. Hozier and Mrs. Taranto are with the Public Health Service in Region VI, Dr. Hozier as general medical consultant and Mrs. Taranto as public health representative.

For comparative studies of program emphasis, however, actual numbers of visits or counts of services to individuals cannot, in most instances, be used, for one type of visit or service may consume several times the amount of time and effort that goes into another. Therefore, the determination of relative emphasis among the many health department programs cannot be made readily from material currently collected or assembled for other purposes.

Time Studies: Pro and Con

For many years, public health workers have been discussing the pros and cons of time studies of public health activities. The most commonly voiced arguments against time studies are that they are too expensive, too complicated in themselves, too time-consuming, or that they are not representative of actual operations if limited in scope and in the period of time covered.

Many time studies have been made which brought forth such a volume of detailed information that funds and personnel were not available to tabulate and analyze the mass of collected material. Also, results of some have proved unsatisfactory partly because of various defects in construction of the form, inadequate instruction of participants, and selection of a period of time not representative of the agency's activities.

Careful planning before the study is begun, however, should eliminate most, if not all, of the factors which are responsible for major criticisms of time studies.

Arguments favoring time studies aver that a time study of public health activities will produce information sorely needed by the public health administrator, specifically the percentage of the agency's total time devoted to each category of service. This information is of inestimable value to the administrator in determining whether or not the programs currently receiving the greatest emphasis are also the programs shown by the State's vital records and other sources of information to be those which should receive the greatest concentration of public health effort.

Mississippi's Objectives

A time study recently completed by the Mississippi State Board of Health dealt with the

activities of all members of the staff and represents a useful approach to time study procedure, particularly in simplicity of execution and in reliability of results.

The immediate objective of the Mississippi time study was the justification of categorical grant expenditures—specifically earmarked funds received by the State board of health from Federal, State, and local sources. An urgent question was being asked: Is the Mississippi State Board of Health properly discharging its obligation to disburse all monies in accordance with Federal and State requirements?

The study was designed to be broad enough in scope not only to serve its immediate purpose but also to provide the basic background data for evaluating the overall State public health program. It was made with what was considered to be a minimum expenditure of time, money, and effort on the part of both participants and directors of the study.

Methodology

The study was made during the fiscal year 1951-52 and involved all employees in the central office of the Mississippi State Board of Health and in the local health departments. Plans for the study were made in consultation with staff members in the local health departments as well as in the central office. Designs for tabulation and analysis were developed well in advance. Every effort was made to define clearly the purposes of the study. Prior to its initiation, group conferences were held with staff members to assure the cooperation of all employees.

Instructions

Written instructions were distributed and explained in detail at these conferences (see pp. 381-385). To avoid confusion in interpretation, definitions used in the instructions conformed to those in the Mississippi daily report of activities with which all local health department personnel were familiar.

That the instructions seemed to be satisfactory to all concerned was indicated by the small number of requests for interpretation during the period of the study and by the apparent accuracy and completeness of the records.

Reminder notices were mailed to all depart-

ments immediately preceding each week of the study.

Daily Time Sheet

The daily time sheet was a single $8\frac{1}{2} \times 11$ -inch tumblehead form with space for recording time under specific activities. Space was provided for daily totals and for central office calculations. Illustrated (p. 382) is a sample of the recorded activities of a clerk-typist in a local health department.

The coding on the reverse of the sheet was performed in the central office. Sheets received from participants were processed as follows:

All sheets were checked against a master list of employees obtained from payroll records to assure completeness of return and to code budget and item numbers. This and other coded information for use of the key punch operator were recorded on the reverse of the sheet. Records for part-time employees were held separately, and an identifying code was placed on them for gang-punching.

Time on the daily sheets was summarized for each individual by weekly totals which were recorded on the sheet for each Monday. Although this process required additional clerical time, it provided a check of the total time recorded and also reduced the volume of punch cards. Errors up to 20 minutes were adjusted in the interrelated column. Sheets with greater discrepancies were returned for correction.

On the basis of experience, it was found that some clerical time could have been saved in the central office if the following changes had been made on the daily time sheet:

Printing of code numbers for activities in calculation space.

Provision of space on reverse side for employees to record budget and item numbers.

Use of 6-minute instead of 5-minute intervals in order to cumulate and to punch the time in hours and decimal fractions of hours instead of minutes.

Punch Card Preparation

A 16-column machine punch card was used on which the budget number was carried in columns 1-3; item number, 4-6; classification of position, 7-8; activity, 9-10; minutes, 11-14; and month, 15-16.

For each employee one card was prepared for each activity listed on the summary time sheet. It was possible, therefore, for as many as 15 cards to have been punched for each employee for a particular week although examination of the records for the first week showed the average to be about 6. It was felt, therefore, that less punching and tabulating time would be required in the procedure followed than if separate fields for each activity were designated on the same punch card. In addition, greater flexibility in tabulating was possible under this procedure.

Tabulations

Preliminary tabulations prepared at the end of each week were used in further checking the accuracy of recorded information and in studying seasonal variations which might determine the duration of the study.

Final tabulations were prepared showing the distribution of time by individual budget elements, by activity, and by classification of position. The budgets were separated into two groups in the tables so that time for central office and time for local health departments are shown separately. In the final tabulations, employees of the State tuberculosis sanatorium and of the rapid treatment centers were excluded because these institutions primarily provide inpatient care. Time reported by the division of vital statistics was omitted from the tabulations because this division is not supported by funds from categorical grants.

Interrelated Time Element

Of the total time, approximately 29 percent was recorded as interrelated, a category which included time spent in general services, leave, and other activities (see instructions) which are necessary to the operation of any public health program. Thus, it was felt that for purposes of studying individual budgets, interrelated time should be allocated to the specific activities by some arbitrary method.

For allocation of interrelated time, budgets were divided into three broad categories: local health departments, central office divisions, and central office supportive services. In the final distribution for local health departments, in-

Continued on page 385.

Mississippi State Board of Health Time Study

—Instructions—

Purpose

To provide a basis and method for the proper and equitable distribution of funds within the budgets of the State offices and cooperating local health departments, with particular reference to the so-called categorical grants covering such specialized activities as maternal and child health, venereal diseases, tuberculosis, heart disease, cancer, mental health, and so forth. It is necessary that the State board of health submit a plan for the next budget period which will justify the expenditure of these funds in the various departments which make use of these monies. This plan must provide satisfactory evidence that services are being rendered at least in proportion to the amount of categorical funds which are included within that budget.

In order to formulate a state-wide plan to meet this request, a comprehensive time study of the activities of all personnel in the State office and county health departments is necessary if we plan to continue at least the present level of health services in the State of Mississippi.

All personnel in the State and local subdivisions of the Mississippi State Board of Health are required to participate.

Explanation and Definition

1 The plan of the study will be as follows: Each worker will keep a daily time study for 1 complete week each month, starting at 8 o'clock Monday morning and continuing through the entire working week. A separate sheet will be filled out for each day through Friday and through the 4-hour work period on Saturday morning. County variations due to midweek closures and working all day Saturday will be adjusted according to the local arrangement. Each worker will be held accountable for a full $5\frac{1}{2}$ -day workweek. The workday will be on the basis of $7\frac{1}{2}$ hours.

2 In order to provide a sample that will take into account weekly as well as seasonal variations in

activities, the study will be kept by weeks as follows until further notice:

4th week in July, beginning Monday, July 23.

1st week in August, beginning Monday, August 6.

2d week in September, beginning Monday, September 10.

3d week in October, beginning Monday, October 15.

4th week in November, beginning Monday, November 26.

Then begin over again with the week of the first Monday in December and so on until the study period is completed. The occurrence of 5th weeks in certain months will be disregarded and not included in this sequence.

3 Every effort has been made to provide a simplified form for this study. The single daily sheet is made up of a heading for identification and coding purposes, followed by a time and an activity table for the period of 8-12 o'clock each day. Space is provided at the bottom of this page for adding the one-half day morning time totals which are to be carried over to the reverse side of the form which covers the afternoon work period from 1 to 4:30 o'clock. At the bottom of the reverse side, another line is provided for the time totals for the entire workday. The remaining space labeled "calculations for central office" is for central office tabulation purposes and is not to be filled out by the workers at either the State or local level.

(See reproduction of form on next page)

4 The vertical time breakdown of the sheet provides major hourly divisions, 15-minute subdivisions, and is finally further subdivided into 5-minute intervals. Therefore, all activities should be designated to the nearest 5-minutes' time insofar as possible. In showing activities of 15 minutes or less, place the symbol "x" in the center of *each 5-minute space* of the time so devoted. For activities exceeding 15 minutes, a vertical line may be drawn down through the center of the proper activity column. However, an "x" should be placed at

Instructions—Continued

5 infants, and 5 venereal disease, the breakdown of the 4 hours should be divided proportionately to service time devoted to those three activities.

6 a. *Name.* Use your official payroll name.

b. *Department or division.* Designate county health department or central office division.

c. *Payroll classification.* Use your official merit system classification which is on the payroll.

d. *Date.* Designate the day of the week and date. For example, Monday, July 2.

e. *Acute communicable disease.* Include all activities that would fall under section A of the tabulation of activities. Time devoted to immunizations in generalized clinics, school clinics, and so forth will be recorded here; also, school inspections for communicable diseases.

f. *Tuberculosis.* Include all activities in section C of the tabulation of activities. The taking of X-rays regardless of what type of clinic they are done in should be listed here. Clerical time in X-ray clinics, working with tuberculosis records or tuberculosis register, and so forth will be allocated to this column.

g. *Venereal disease.* Include all activities in section B of the tabulation of activities. Time estimated in taking of blood tests, or seeing patients relative to venereal disease in any type clinics whether it be maternal and child health, food handlers, and so forth will be coded to this column.

h. *Cancer.* Include time spent on special cancer clinics, on visits to cancer patients, special examinations, education, and so forth, in connection with State cancer control programs.

i. *Maternal and child health:*

1. *Maternity*—Include time covering those activities listed in tabulation of activities.

2. *Infant*—Include time covering those activities listed in tabulation of activities.

3. *Preschool*—Include time covering those activities listed in tabulation of activities.

4. *School*—Include time covering those activities listed in tabulation of activities.

j. *Mental health.* Include time spent in special clinics, home visits, and special examinations in connection with State mental hygiene program.

Lunacy hearings should also be coded in this section.

k. *Heart disease.* Include time spent in special clinics, home visits, and special examinations in connection with State heart disease control program.

l. *Adult hygiene.* Include here the items as included in section H of the quarterly tabulation of activities except service to cancer and heart patients which have a special column. General type food handler clinics will fall in this category.

m. *Industrial hygiene.* County personnel who are called on to do special industrial hygiene inspections, investigations, or surveys within their own county as a part of the State industrial hygiene service will code activities in this column.

n. *Sanitation.* In general the major part of the sanitation supervisor's activities as listed in the quarterly tabulation of activities section J will be reported here. Environmental typhus and malaria activities and other special projects, unless otherwise instructed, will also be coded here. When the sanitation supervisor renders service in acute communicable disease control, tuberculosis control, or other health activities with the health officer, nurse, and other members of the staff, these services should be carefully evaluated and credited to the proper category. The health officer, nurse, clerk, and other members of the staff will also use the sanitation column on occasions if their activities are evaluated in the field of sanitation.

o. *Water pollution.* There shall be recorded in this column all time devoted to water pollution control activities; that is, any work carried on by an individual relating to stream sanitation studies, investigations of existing municipal sewage or industrial waste treatment plants, investigations made for the purpose of securing the installation of a municipal sewage or industrial waste treatment plant, and activities related to removal of pollution from any streams, lakes, or coastal waters of the State. This includes time performed by any county sanitation supervisor individually or in company with a representative of the division of sanitary engineering.

p. *Interrelated.* This column should not be abused. Some general administrative items that will fall into this classification are contacts with boards and other officials unless the meeting is for a specific purpose; answering the telephone and meeting the public; preparing of financial reports; administrative correspondence; preparation of quar-

terly reports and narratives; preparation of personnel records and handling of personnel problems; preparation of leave requests; staff conferences for program review or planning; and conferences with lay groups or clubs unless a specific subject or talk is given.

Clerical time has been covered in some of the above listed administrative activities; however, when possible, specific work on certain records, such as immunization cards, tuberculosis records, venereal disease records, milk ledgers, and so forth, should be properly charged to the appropriate column. General indexing, checking and filing of daily reports, recording of laboratory data, vital statistics activities, and other programs that cover multiple health activities should be charged to the interrelated column.

General Remarks

1 Travel time. The time going to and returning from a particular activity, clinic, or series of home visits, or inspections, if they are in the same category, will be charged against it. However, in the instance of multiple home visits or inspections where the category or purpose may vary from visit to visit, going to the first premise will be charged to the purpose of that visit; between visit 1 and visit 2, to the purpose of the second visit; and so forth. The return time following the last visit of such a series will be charged to interrelated activity. Travel to and from an outlying mixed general type of clinic will be charged to interrelated.

2 Leave time. All leave time will be charged to interrelated activity.

3 Lost time. When a patient or individual is not located or not at home, this time will be charged to the planned activity or original purpose of the effort.

4 Overtime. No overtime will be coded. All activities will be limited to the hours of the official workday.

5 Preparation time and posting time. Such preparation for a clinic or visit will be charged against the major service given during this activity, or allocated proportionately to the time given to the specific activity.

6 Classes, lectures, movies, exhibits, and so forth. Code this time against the category you consider received the major interest during the activity.

7 Lunch hours. In many departments lunch hours are staggered. Since a 12-1 o'clock interval is not provided for coding worktime, bring the work period backward or forward as the case may be so that it is tabulated between 11-12 or 1-2. For example, personnel taking off for lunch from 11:30-12:30 will list the half hour 12:30 to 1 o'clock as occurring between 11:30 and 12:00. Morning and afternoon breaks for rest period should be charged to interrelated.

8 Special and part-time personnel. Label all part-time forms with notation P-T in parentheses by payroll classification.

a. *Health educators.* These activities are sufficiently diversified, so that careful evaluation should be given in coding their activity time properly according to the quarterly tabulation of activities.

b. *Laboratory workers.* This work falls principally into the fields of acute communicable disease control, venereal disease, tuberculosis, maternal and child health, and sanitation, with some specialized activities in certain areas in connection with shellfish control and stream pollution. Code accordingly.

c. *Veterinarians.* Both full- and part-time personnel will be included in the study. The major part of these activities will be coded under sanitation but on occasion certain activities if properly evaluated should be coded under communicable disease, such as rabies control or other epidemiological investigations.

d. *Nurses aides and clinic technicians.* Full-time, part-time or those working on an hourly basis will maintain their own study records.

e. *Dental hygienist and dentist.* This activity is primarily in the field of maternal and child health or school health. Dental hygienists will be held responsible for the reporting of all dental service time.

f. *Venereal disease investigator.* These activities will for the most part be coded under venereal disease control as listed in section B of the quarterly tabulation of activities. However, when taking part in other special projects, these should be accounted for under the proper category.

g. *Special administrative, special clerical, and part-time administrative or clerical personnel.* These are usually concerned with specific activities

or projects and should be coded as indicated. However, general service personnel in the above category can list their activities under interrelated unless otherwise instructed.

h. *Porters and maids.* Charge to interrelated unless employed for special purpose or special clinic.

Office Mechanics and Filing

1 Each person will be held responsible for the neatness, accuracy, and completeness of his own time study sheet. The daily time sheets will be kept by the individual concerned until all the sheets for the week are complete. Each worker will be responsible for *checking* the accuracy of the information and the time totals at the end of each daily sheet, which should be added horizontally across the column marked daily total. This total *will not be*

more nor less than 450 minutes for a full workday and will be 240 minutes for a half day.

2 On Monday of the week following the study, the completed forms in proper daily sequence will be turned over to the responsible health officer or secretary or clerk for checking their completeness and to see that all personnel in the department have been accounted for. The responsible health officer or clerk will *be sure to recheck the items* mentioned in paragraph 1, namely the accuracy of the heading and daily totals.

3 The forms for the entire department will be mailed or delivered to the division of county health work, arranged in daily sequence and properly separated by individuals for the entire week, so as to reach the division of county health work not later than 1 week after the end of the completed study week.

Continued from page 380.

terrelated time was distributed according to the percentage distribution of total identified time for all counties combined. In the central office, interrelated time for each division except for selected supportive services was distributed according to the percentage distribution of identified time in that division. Interrelated time in the supportive services—administration office, business office, statistical service, county health administration, personnel office, and merit system—was allocated according to the distribution of all identified time in the central office.

In future analyses, interrelated time reported by the division of vital statistics will be distributed on the same basis as that for the supportive services.

If the purpose of the study were expanded to include more detailed examination of program content, additional subdivisions might be used to account for major activities included in interrelated time, for example, sick and annual leave, and general administration.

Findings of the Study

The comparatively uniform distribution of activity time prompted discontinuation of the study after 8 sample weeks, 1 each in July–December (1951) and January and February

(1952). The number of employees varied only slightly during this period with the smallest number, about 795, in October and the largest number, about 810, in July. These employees reported 15,946,165 minutes—or 265,769 hours—for the 8 weeks.

Time Distribution

Final distribution of time and percentages for the various activities are shown in table 1. As was expected, there were wide variations in distribution both in the local health departments and in the central office. Because of the assignment to central office budgets of some employees who serve at the local level, venereal disease investigators and mobile X-ray personnel for example, time and percentage proportions in the central office for several activities exceeded proportions in local health departments.

The percentage distribution of time in local health departments by program activity and by personnel category is shown in table 2. In general, the time for medical, nursing, and clerical personnel was spread throughout all activities and did not show as much concentration as did the time for personnel classified as sanitation, dental, and health education.

individual health departments, but the wise administrator will investigate to find out why one department spent only 4.4 percent of its time on acute communicable disease and why another county spent 24.4 percent; why the range for venereal disease was from 3.1 to 24.0 percent and for sanitation, from 6.2 to 44.0 percent.

It is planned to make such tabulations of activities by counties available to the local health departments and to assign each county a tabulation number known only to itself.

Sampling Investigations

The percentage distributions of time in local health departments by activity for each week are shown in table 4. The relative uniformity in the last six sample weeks will be noted. In this study, average deviations from the total distribution were smallest during the first week in December and during the second week in September. Relatively small deviations also occurred during the second week in January, the third week in February, the fourth week in November, and the third week in October. It is likely that the larger variations which occurred during the fourth week in July and the first week in August were due to seasonal circumstances and not to the choice of week. Larger proportions of interrelated time were recorded in these months because of employee vacations. Also, relatively little time was assigned to school activities because few schools were in session.

Policies of the State board of health probably influence many of the variations. Examinations of school children are customarily made in October and November of each year, and the proportions in table 4 reflect this increased activity. Time spent on tuberculosis control varied in part because of reduction in mobile screening services during the fall months when equipment was undergoing repair. Immunizations and epidemiological investigations of acute communicable diseases increased the time spent on this category during the summer months. Venereal disease activity was highest during the first 3 weeks of the study in agreement with the increase noted in other venereal disease reports for this time

of the year. The variations in sanitation time were small and did not follow a trend. Since most time in this category was contributed by personnel assigned to sanitation, a relatively stable group, the slight changes may have occurred because of special sanitation activities performed by other personnel groups. The time for cancer activities was relatively high during the fall, especially in October, when many of the public health nurses attended in-service training courses in cancer.

Valid Sample Week

The distributions, especially uniform during the last 6 sample weeks, indicate that a reasonably accurate estimate of total local health department time could have been obtained if the study had been limited to any one of the last 6 sample weeks. From a practical standpoint, the second week in September would probably be the period of choice in Mississippi.

The weekly variations in the central offices were smaller than those in the local health departments, and any one of the 8 weeks would have furnished a satisfactory distribution of time.

Table 5. Mississippi time study: Distribution of time by activity for sample composed of every fifth local health department budget, and for all local health departments combined—8 weeks during July 1951–February 1952

Activity	13-county sample		All local health departments (percent)
	Minutes	Percent	
Total.....	1, 833, 980	100. 0	100. 0
Acute communicable disease.....	200, 839	11. 0	11. 2
Tuberculosis.....	194, 908	10. 6	10. 1
Venereal disease.....	192, 959	10. 5	9. 7
Cancer.....	26, 772	1. 5	1. 1

Water pollution.....	5, 546	. 3	. 1

Size of Population

To check the validity of further sampling, the punch cards were sorted in terms of the local health department budgets. They were arranged in order of population size of the counties, and every fifth health department was selected. By this method, 11 county or district health departments were chosen including 13 of the 80 counties with full-time health departments and an aggregate population of 379,296, or about 18 percent of the State population served by local health departments.

Employee time in this group is shown in table 5. Some changes from the distribution for all departments will be noted, but the percentages for this sample furnished another estimate of activity distribution which may be adequate for practical purposes. This estimate, however, did not agree so closely as the single weeks in September, November, December, January, or February agreed with the total distribution.

The selection of the sample probably introduced some bias. Although this sample was based on population, and the rural-urban composition was approximately the same as for the entire State, the sample was somewhat weighted with nonwhites. However, this did not cause any apparent deviations in activity time.

The only consistent difference was in the proportion for sanitation activities. This percentage was lower in the selected counties than in the entire State for every week of the study, as a comparison of tables 4 and 6 will show.

Evidently, a sample of counties based on population size of counties does not provide a representative sample for sanitation activities since problems in this category are less likely to be directly related to the number of persons than in other categories. In this sample, for example, little shellfish sanitation, no military installations, and no high milk-producing areas were included, and consequently, important parts of the sanitation program were omitted.

The weekly distributions for this sample are shown in table 6. In these distributions, as in the total, the average deviations were highest during the fourth week in July and the first week in August and lowest during the other 6 weeks of the study. All these deviations are greater than those for single weeks for all employees and also for the 8 weeks combined for the sample group of counties. An estimate of activity time, however, could have been made from a time study of every fifth county according to population size for a period of only 1 week. And, further reductions in the sample could have been made. In the other samples

Table 6. Mississippi time study: Percentage distribution of time by activity by week of study for sample composed of every fifth local health department budget—8 weeks during July 1951—February 1952

NOTE: Interrelated time in each week was distributed according to the distribution of identified time in that week.

illustrated here, some accuracy has been sacrificed; that is, the smaller the sample, the greater the error.

Of the four estimates of activity distribution shown, the most accurate is assumed to be the one based on total employees for the entire 8 sample weeks (table 2).

Summary and Conclusions

The Mississippi time study included all State and local health department employees for a period of 8 sample weeks. It produced with what is considered to be a minimum expenditure of time and effort the information for which it was designed: factual data for the justification of categorical grant expenditures; and information for crude evaluation of program activities.

On the basis of the crude evaluations of sev-

eral of the larger programs, there is evidence of the need for further study in these areas.

Analysis indicates that a reasonably accurate estimate of total time distributions could have been obtained if the study had been further limited in time to any 1 of the last 6 sample weeks. An estimate of activity distribution procured by limiting the study in area did not agree so closely with the total distribution as did the single weeks. However, even this variation is not necessarily great enough to preclude the use of smaller areas in studies of this kind. Apparently, a reasonably accurate estimate of time devoted to the various health department activities can be obtained from a study made on the basis of a relatively short period of time, probably without including the entire State and local staffs.

Public Health Service Staff Announcements

Dr. Louis L. Williams, Jr., a career officer of the Public Health Service since 1915 and chief of the Division of International Health since 1948, retired January 31, 1953. A specialist in malaria control research, Dr. Williams long directed Public Health Service malaria investigations. He served as field director of rural malaria control investigations in Virginia from 1921 to 1930 and was in charge of malaria studies at the National Institutes of Health from 1926 to 1940. Before World War II, Dr. Williams headed the malaria commission to China-Burma Highway, and at the war's start he organized malaria control in areas of camps and war industries. In 1943, he was detailed to the U. S. Army as malariologist in the Mediterranean Theater of Operations.

From 1945 to 1948, Dr. Williams was Public Health Service liaison officer to the Department of State, assisting in organizing its international health affairs branch. He was a member of the United States delegation to the International Health Conference, which in 1946 drew up the constitution of the World Health Organization. He also served as a delegate to the Pan American Sanitary Conference in Caracas in 1947 and as a member of the organizing committee, Fourth International Congress on Tropical Medicine and Malaria, in 1947.

Dr. H. Trendley Dean, director of the National Institute of Dental Research, National Institutes of Health, Public Health Service, retired April 1, 1953. A pioneer in research leading to the use

of fluoridated water to reduce dental decay in children, Dr. Dean made the discovery that people using fluoride drinking water had teeth that resisted decay. He has been a Public Health Service officer since 1921, and in recent years at the National Institutes of Health he directed a broad program of investigation into the diseases of softening tissues, pyorrhea, and other oral conditions.

Dr. Dean's interest in the relationship of fluoride to dental caries grew out of his earlier work on mottled enamel. Dr. Dean was assigned in 1931 to determine where in the United States people drank water containing fluoride and how it caused dental fluorosis—mottled enamel. In 1942, after a study of 21 cities, he and his colleagues at the National Institutes of Health were able to determine that one part of fluoride to a million parts of water was sufficient to inhibit dental decay without causing fluorosis.

Dr. Francis A. Arnold, Jr., associate director of the National Institute of Dental Research since 1948, has been named as the new director. Dr. Arnold, who has been with the Public Health Service since 1934, has worked with Dr. Dean since the first studies on the relationship of fluoride to dental caries were made in 1937. He made the first report on production of carious teeth in hamsters, these animals having since become one of the principal experimental animals in this work.

Twenty Years of Followup Experience In a Long-Range Medical Study

By EUNICE RIVERS, R.N., STANLEY H. SCHUMAN, M.D., LLOYD SIMPSON
and SIDNEY OLANSKY, M.D.

ONE OF THE longest continued medical surveys ever conducted is the study of untreated syphilis in the male Negro. This study was begun by the Public Health Service in the fall of 1932 in Macon County, Ala., a rural area in the eastern part of the State, and is now entering its twenty-second year (1-4). This paper is the first report dealing with the nonmedical aspects of the study. The experiences recounted may be of value to those who are planning continuing studies in other fields.

In beginning the study, schedules of the blood-drawing clinics throughout the county were announced through every available source, including churches, schools, and community stores. The people responded willingly, and 600 patients were selected for the study—400 who had syphilis and, for controls, 200 who did not. The patients who had syphilis were all in the latent stage; any acute cases requiring treatment were carefully screened out for standard therapy.

Miss Rivers, a public health nurse with the Division of Venereal Disease, Public Health Service, is associated with the Macon County Health Department, Tuskegee, Ala. Mr. Simpson is a venereal disease field investigator for the Public Health Service in Region VI. Dr. Schuman is with the clinical investigations section of the Venereal Disease Research Laboratory in the Communicable Disease Center, Chamblee, Ga., and Dr. Olansky is director of the laboratory.

At Tuskegee, each of the 600 patients initially was given a complete physical examination, including chest X-rays and electrocardiograms. Careful histories were taken and blood tests were repeated. Thereafter, each of the patients was followed up with an annual blood test and, whenever the Public Health Service physicians came to Tuskegee, physical examinations were repeated.

There have been four surveys: in 1932, 1938, 1948, and 1952. Between surveys contact with the patients was maintained through the local county health department and an especially assigned public health nurse, whose chief duties were those of followup worker on this project. The nurse also participated in a generalized public health nursing program, which gave her broad contact with the families of the patients and demonstrated that she was interested in other aspects of their welfare as well as in the project. The nurse was a native of the county, who had lived near her patients all her life, and was thoroughly familiar with their local ideas and customs.

A most important phase of the study was to follow as many patients as possible to post-mortem examination, in order to determine the prevalence and severity of the syphilitic disease process. Cooperation of patients with this plan was sought by offering burial assistance (through a private philanthropy, the Milbank Memorial Fund) on condition that permission be granted for autopsy. For the majority of these poor farmers such financial aid was a real boon, and often it was the only "insurance" they

could hope for. The Federal Government offered physical examinations and incidental medication, such as tonics and analgesics, but was unable to provide financial assistance on a continuing basis. The Milbank Memorial Fund burial assistance made it possible to obtain a higher percentage of permissions for post-mortem examinations than otherwise would have been granted.

Transportation to the hospital for X-rays and physical examination was furnished by the nurse. Her car was too small to bring in more than two patients at one trip; therefore, two men were scheduled for examination in the morning and two for the afternoon. During the early years of the study, when the county was strictly a rural one, the roads were very poor, some being impassable during the rainy season. Very often, the patients spent hours helping to get the car out of a mudhole. Now, with modern conveniences (telephones, electricity, cars, and good roads) the nurse's problems are fewer than in the early days.

Having a complete physical examination by a doctor in a hospital was a new experience for most of the men. Some were skeptical; others were frightened and left without an examination. Those who were brave enough to remain were very pleased. Only one objection occurred frequently: the "back shot," never again! There are those who, today, unjustifiably attribute current complaints (backaches, headaches, nervousness) to those spinal punctures.

Followup

The patients have been followed through the years by the same nurse but by different doctors. Some doctors were liked by all the patients; others were liked by only a few. The chief factor in this was the length of time doctor and patients had to get to know each other. If the doctor's visit to the area was brief, he might not have time to learn and to understand the habits of the patients. Likewise, the patients did not have an opportunity to understand the doctor. Because of their confidence in the nurse, the patients often expressed their opinion about the doctor privately to her. She tried always to assure them that the doctor was a busy

person interested in many things, but that they really were first on his program.

It is very important for the followup worker to understand both patient and doctor, because she must bridge the gap between the two. The doctors were concerned primarily with obtaining the most efficient and thorough medical examination possible for the group of 600 men. While they tried to give each patient the personal interest he desired, this was not always possible due to the pressure of time. Occasionally, the patient was annoyed because the doctor did not pay attention to his particular complaint. He may have believed that his favorite home remedy was more potent than the doctor's prescription, and decided to let the whole thing go. It then became the task of the nurse to convince him that the examinations were beneficial. If she failed, she might find that in the future he not only neglected to answer her letters but managed to be away from home whenever she called. Sometimes the doctor grumbled because of the seemingly poor cooperation and slowness of some of the patients; often the nurse helped in these situations simply by bridging the language barrier and by explaining to the men what the doctor wanted.

Sometimes the nurse assisted the physician by warning him beforehand about the eccentricities of the patients he was scheduled to see during the day. For example, there was the lethargic patient with early cancer of the lip who needed strong language and grim predictions to persuade him to seek medical attention. On the other hand, there was the hypochondriac who overheard the doctor mention the 45° angle of rotation of his body during the X-ray examination; the next day, the entire county was buzzing with gossip about their remarkable friend who was "still alive, walking around with his heart tilted at a 45° angle."

Following a group of patients in a specialized field over a period of years becomes monotonous to patient and nurse, and both could lose interest easily. For the patients, the yearly visits by the "Government doctor," with free medicines, revived their interest. The annual blood tests and the surveys were always scheduled at "slack" times, between fall harvest and spring planting. The patients congregated in groups at churches and at crossroads to meet the nurse's

car in the morning. As the newness of the project wore off and fears of being hurt were relieved, the gatherings became more social. The examination became an opportunity for men from different and often isolated parts of the county to meet and exchange news. Later, the nurse's small car was replaced with a large, new, Government station wagon. The ride to and from the hospital in this vehicle with the Government emblem on the front door, chauffeured by the nurse, was a mark of distinction for many of the men who enjoyed waving to their neighbors as they drove by. They knew that they could get their pills and "spring tonic" from the nurse whenever they needed them between surveys, but they looked forward happily to having the Government doctor take their blood pressure and listen to their hearts. Those men who were advised about their diets were especially delighted even though they would not adhere to the restrictions.

Because of the low educational status of the majority of the patients, it was impossible to appeal to them from a purely scientific approach. Therefore, various methods were used to maintain and stimulate their interest. Free medicines, burial assistance or insurance (the project being referred to as "Miss Rivers' Lodge"), free hot meals on the days of examination, transportation to and from the hospital, and an opportunity to stop in town on the return trip to shop or visit with their friends on the streets all helped. In spite of these attractions, there were some who refused their examinations because they were not sick and did not see that they were being benefited. Nothing provoked some of the patients more than for a doctor to tell them that they were not as healthy as they felt. This attitude sometimes appeared to the examining physician as rank ingratitude for a thorough medical workup which would cost anyone else a large amount of money if sought at personal expense. At these times the nurse reminded the doctor of the gap between his education and health attitudes and those of the patients.

When a patient asks the nurse for help because he is a "Government patient" and she explains there are no funds for this, he may point out that he needs assistance while he is living, not after he is dead. Whenever the nurse

A Career in Nursing Service

Miss Rivers knows her patients well. She was born in Georgia and has lived in that vicinity her entire life. After graduation from the Tuskegee Institute School of Nursing in 1922, she joined the Alabama State Department of Health. There she was assigned to the bureau of maternal and child welfare where she helped farmers and their wives in the rural areas of Alabama with problems of home nursing and home hygiene. In a later assignment with the Alabama bureau of vital statistics, she assisted midwives in problems of rural nursing and in their vital statistics reports. After 8 years of work for the State, she returned to Tuskegee to be night supervisor of the John A. Andrew Memorial Hospital.

In 1932, Miss Rivers was offered a position as night supervisor in a New York general hospital. She chose, instead, to stay in Alabama as a scientific assistant with the Division of Venereal Disease of the Public Health Service. Miss Rivers still holds this position, in which she cooperates with the physicians and contact investigators on the Tuskegee untreated syphilis study. She also is the contact worker with the venereal disease control program in addition to assisting in the general nursing service of the Macon County Health Department.

Among her deepest convictions is the belief that rural areas desperately need good and sympathetic nurses to participate in and carry out effectively public health programs, as well as private medical care. She feels very strongly, on the basis of her own experience, that the girl who is trained in nursing in a rural area is much more likely to live and practice nursing in that area. Miss Rivers feels that, had she taken the offer to go to New York City many years ago, she probably would never have returned to the people with whom she is so familiar and for whom she feels she now can do her small part to contribute to better health and advances in public health.

heard this complaint, she knew that there was danger of a lost patient. She appealed to him from an unselfish standpoint: What the burial assistance would mean to his family, to pay funeral expenses or to purchase clothes for his orphaned children. Even though a large number wished they might derive more benefits

from being "Government patients," most of them answered the call to meet the doctor, some willingly, others after much persuasion.

The study group was composed of farmers who owned their homes, renters who were considered permanent residents, and day laborers on farms and in sawmills. The laborers were the hardest to follow. Some of the resident farmers traveled to other sections seeking work after their own crops had been harvested, but they came back when it was time to start planting. An effort was made continually through relatives to keep informed of the patients' most recent addresses, and this information regularly has been placed in their records. During the 20 years of the study, 520 of the original 600 men have been followed consistently if living, or to autopsy. It is possible that some of the 80 now considered lost will at some time return to the county or write the nurse from distant places for medical advice.

Autopsies

The excellent care given these patients was important in creating in the family a favorable attitude which eventually would lead to permission to perform an autopsy. Even in a friendly atmosphere, however, it was difficult for the nurse to approach the family, especially in the early years of the project, because she herself was uneasy about autopsies. She was pleasantly surprised to receive fine response from the families of the patients—only one refusal in 20 years and 145 autopsies obtained. Finally, the nurse realized that she and not the relatives had been hesitant and squeamish.

Sometimes the family asked questions concerning the autopsy, but offered no objections when they were assured that the body would not be harmed. If the patient had been ill for a long time and had not been able to secure any relief from his symptoms, they were anxious to know the reason. If he had died suddenly, they were anxious for some explanation. They also feared that some member of the family might have the same malady, and that information learned from the autopsy might aid them. Now, after many years, all of the patients are aware of the autopsies. When a member of "Miss Rivers' Lodge" passes, his sur-

living colleagues often will remind the family that the doctor wants "to look at his heart." Autopsies today are a routine; neither nurse nor family objects.

One cannot work with a group of people over a long period of time without becoming attached to them. This has been the experience of the nurse. She has had an opportunity to know them personally. She has come to understand some of their problems and how these account for some of their peculiar reactions. The ties are stronger than simply those of patient and nurse. There is a feeling of complete confidence in what the nurse advises. Some of them bring problems beyond her province, concerning building, insurance, and other things about which she can give no specific advice. She directs them always to the best available sources of guidance. Realizing that they do depend upon her and give her their trust, she has to keep an open mind and must be careful always not to criticize, but to help in the most ethical way to see that they get the best care.

Conclusions

Experience with this project has made several points clear which may benefit anyone now engaged in planning or executing a long-range medical research study:

1. Incentives for maximum cooperation of the patients must be kept in mind. What appears to be a real incentive to an outsider's way of thinking may have little appeal for the patient. In our case, free hot meals meant more to the men than \$50 worth of free medical examination.

2. The value of rapport and sympathy between patient and physician, and between patient and nurse or followup worker never can be overestimated. Material incentives can merely supplement and support a basic feeling of good will. A kind word is often worth a carton full of free medicines. A single home visit is worth more than a dozen letters on impressive stationery.

3. Changes in key personnel over the years in a long-range project can seriously weaken the project by upsetting continuity and familiar routine. It is not amiss to start a long-

range study with young personnel who should then be around for the conclusion of the project. On the other hand, some new personnel may bring fresh ideas and energies to a lagging effort.

4. Teamwork between all members of the research staff is essential: doctor, nurse, investigator, technicians, and clerks all must work together for a common goal. They must appreciate the importance of each other's efforts to the success of the whole.

5. As difficult as it may be to maintain patient interest and personnel efficiency in a long-term study, there is still the advantage of momentum which gathers slowly but increasingly, until patient cooperation becomes so routine as to be habitual. Difficulties often can be anticipated due to previous experience, and thereby avoided.

6. The gains to medical knowledge derived from the horizontal, long-term study of illness and health are only just beginning to be real-

ized. As public health workers accumulate experience and skill in this type of study, not only should the number of such studies increase, but a maximum of information will be gained from the efforts expended.

Annual Symposium on Venereal Diseases

The annual symposium on Recent Advances in the Study of Venereal Diseases, sponsored by the experimental therapeutics study section of the National Institutes of Health, Public Health Service, will be held at the Federal Security Building in Washington, D. C., April 30 through May 1, 1953. The symposium will take place in conjunction with the 15th annual session of the American Venereal Disease Association.

All scientific workers interested in this field, including biologists, physicians, representatives of industry, epidemiologists, and public health nurses, are invited to attend. Further information may be obtained from Dr. Frederick W. Appel, executive secretary, experimental therapeutics study section, National Institutes of Health, Bethesda 14, Md., or from Dr. John C. Hume, secretary, American Venereal Disease Association, 615 N. Wolfe Street, Baltimore 5, Md.

Child Health Day

May 1, 1953

In the quarter century since President Coolidge issued the first Child Health Day Proclamation, through new medical and scientific discoveries and extensive public health work, our country has made tremendous advances in overcoming many of the great physical hazards which used to threaten children.

In the words of President Eisenhower, "We are now striving to make equally significant progress in understanding the nature of emotional health, in order that our children may grow into mature, responsible citizens of a democracy."

We know that children who do not get the chance to develop their fullest capacities in each stage of their growth run larger risks of growing into maladjusted, unhappy, and not fully productive adults.

All along the way we see evidence that the knowledge we have about child growth is not being fully applied. We see it in mounting juvenile delinquency rates, in a fantastically large national crime bill, in mounting numbers of emotionally disturbed, mentally ill people.

There is nothing that leads us to believe that people are born juvenile delinquents or criminals. And it is in their childhood that tendencies in these directions first appear.

If, as parents, we can understand more about the growth processes of childhood, we increase the chances that our children can develop the emotional and mental strength required to live happy, useful, and satisfying lives.

OVETA CULP HOBBY

Secretary, U. S. Department of Health, Education, and Welfare

A PROCLAMATION

By the President of the United States
Of America

WHEREAS the Congress, by a joint resolution of May 18, 1928 (45 Stat. 617), authorized and requested the President of the United States to issue annually a proclamation setting apart May 1 as Child Health Day; and

WHEREAS the health and wholesome development of our children are matters of the deepest concern to all Americans; and

WHEREAS the stresses and strains of our times create many problems bearing on the spiritual and emotional health of our children and are reflected notably in juvenile delinquency; and

WHEREAS we have made tremendous advances in overcoming the most severe physical hazards of childhood, and are now striving to make equally significant progress in understanding the nature of emotional health, in order that our children may grow into mature, responsible citizens of a democracy:

NOW, THEREFORE, I, DWIGHT D. EISENHOWER, President of the United States of America, do hereby designate the first day of May, 1953, as Child Health Day; and I urge all parents and young people, and all other individuals, as well as agencies and organizations interested in the well-being of children, to increase their understanding of the emotional, social, and spiritual growth of children, so as to apply this understanding in their day-to-day relations with the rising generation.

IN WITNESS WHEREOF, I have hereunto set my hand and caused the Seal of the United States of America to be affixed.

DONE at the city of Washington this 20th day of February, in the year of our Lord nineteen hundred and fifty-three, and of the independence of the United States of America the one hundred and seventy-seventh.

DWIGHT D. EISENHOWER.

Maternal and Child Health Services

—Challenges and Aims—

By LEONA BAUMGARTNER, M.D., Ph.D.

MATERNAL and child health activities, which had their beginnings far, far back in human history, have grown through the years with the technological advances and the changing social attitudes of the times. It is no more possible to predict exactly what direction they will take in the future than it would have been 25 years ago to outline today's program. Nor is the making of specific predictions a wise procedure, for public health programs must be flexible to allow for the inevitable social and technological changes. However, it is possible and it is wise to chart some sort of course for the future. An examination of the existing situation in maternal and child health—the achievements that have been made and the problems still to be solved—provides a basis for suggestions for future action.

Maternal and Infant Mortality

The greatest and most obvious achievement has been the saving of lives of infants and moth-

Dr. Baumgartner has been associated with the New York City Department of Health since 1937 and now as assistant commissioner directs its maternal, child, and school health services. In 1945 she was adviser to the French Ministry of Health, and in 1949-50 she served as associate chief of the Children's Bureau, Federal Security Agency. She is a member of the faculty of the Cornell University Medical College and of the Harvard School of Public Health.

This paper is based on material presented at the 48th annual New York State Health Conference at Lake Placid, June 1952.

ers. Since 1915, the infant death rate among registered births in the United States has decreased 67 percent for the first year after birth, 80 percent for the second through the twelfth month, 52 percent for the first month, and 31 percent for the first day.

Fetal deaths too seem to have decreased. At least, the number of fetal deaths after 28 weeks of gestation now equals the number of neonatal deaths. Progress has also been made in saving the prematurely born, among whom the death rate has declined about 33 percent since 1915. Maternal death rates have dropped phenomenally, 85 percent since that date.

Despite these successes, fetal, neonatal, and maternal deaths year after year constitute the third or fourth largest group of deaths among the total population. Much more needs to be known about how to prevent these deaths, and much more needs to be done to put into practice what is already known. It is discouraging to see, for example, that although fewer mothers die as a result of childbearing, they still die largely of preventable causes—hemorrhage, infection, toxemia.

The infant death problems are now primarily centered around deaths at or near birth. The strong probability that certain groups in the population give rise to a large proportion of the fetal and neonatal deaths indicates these groups as one place in which activities should be concentrated. The medical factors leading to pregnancy wastage obviously need further elucidation, but it should not be forgotten that the social and economic factors also may be important.

A specific area in which additional knowl-

edge is needed is deaths of premature infants, which constitute about two-thirds of all infant deaths. Although intensive study in the past two decades has developed methods of saving the lives of these infants and large programs for their care have been inaugurated, the lack of information on how to prevent premature labor has so far precluded the establishment of a truly preventive program.

Child Health and Rehabilitation

A second noteworthy achievement is the improved health of children after infancy. The communicable diseases are largely under control, with enormous reductions in the mortality, morbidity, and crippling they once caused. In fact, so successful have been the efforts in this direction that accidents now kill more children from 1 through 15 years of age than disease.

Much still remains to be done, however. Little knowledge exists, for example, as to where or how to begin to solve the accident problem. And conditions which formerly received little or no attention—such as epilepsy, congenital heart disorder, cerebral palsy—can now be attacked.

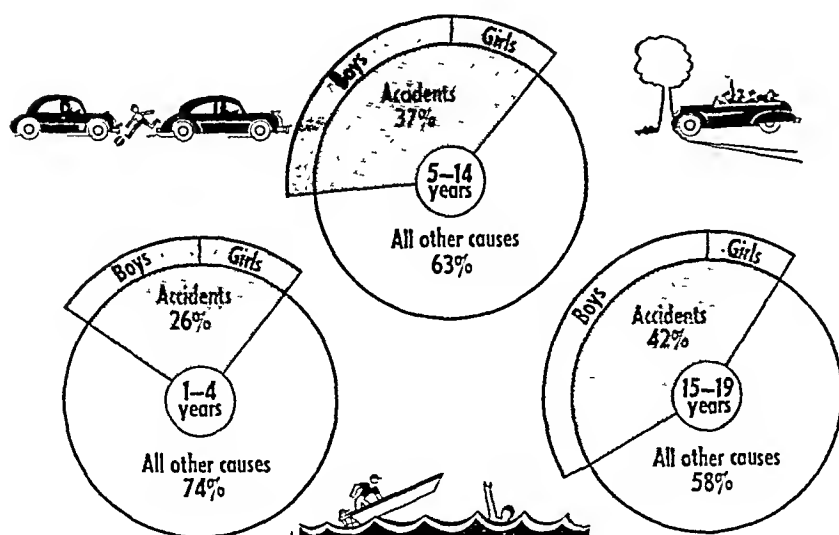

Rehabilitation of children with handicaps or chronic diseases presents many problems. The public must be willing to support the community-wide activities of case finding, diagnosis, and therapy that are essential if maximum rehabilitation is to be secured for all. These ac-

tivities are usually complicated, demanding the cooperation of more than one professional group. Few communities have so organized their resources as to make them easily available on an inclusive basis. Very real experimentation must be undertaken if all children are to have the services they need for full utilization of their assets.

Further, rehabilitation activities are not always undertaken in accord with the expectation of greatest results. Public demand seems largely to have decided what was to be done. For example, few communities have attempted to establish rehabilitation of the epileptic child, even though it appears possible to improve the condition of over 80 percent of epileptic persons at relatively little cost.

Promotion of Health

A third achievement is the enormous body of specific knowledge about the physical, mental, and emotional growth and development of children obtained through research during the past four or five decades. Research has provided many, apparently unrelated facts indicating how children differ from adults and from each other. Physical growth seems to proceed in a more or less orderly fashion according to a general pattern, but within this pattern each individual proceeds at his own pace and in his own way. A pattern is evident, too, in emotional and behavior development. Permeat-

Accidents

are the greatest hazard in the lives of children. In 1948—the year on which the chart data are based—16,000 persons under 19 were killed by accidents. And the number of deaths tell only part of the story. Many more thousands of children were handicapped by accidental injury.

Good medical and nursing care throughout pregnancy—with supportive instructional and educational programs for parents before and after delivery—and the provision of good hospital facilities means the saving of thousands of babies and mothers. Achievements in reducing maternal deaths have been impressive,

ing the conclusions drawn from studies of all types is the concept of "readiness," that is, that the most successful attempts to train a child, to modify his behavior, are those which are timed to coincide with an appropriate stage of his development.

Particularly important for the public health expert are the clues as to the kinds of experience and environment which promote or retard optimal growth of the individual. These clues can be considered as hints for carefully planned epidemiological studies. The control of typhoid fever, for example, came after the lead provided by the Broad Street pump incident almost 100 years ago. Surely the environment can and should be controlled to promote the health of the child in other ways, and the process may well lead to results as spectacular as those achieved through improved environmental sanitation.

Social and Economic Factors

Certain economic and social factors which affect families and children should also be considered. Although these factors are not usually given attention by the medical and public health professions, they are certainly not re-

reflected in all three major causes—infection, toxemia, hemorrhage—a result largely of prenatal care plus hospital deliveries. Yet even now 1 out of 3 Negro babies is born with no medical attendance, and the needs today are greatest among Negro mothers and mothers living in rural areas.

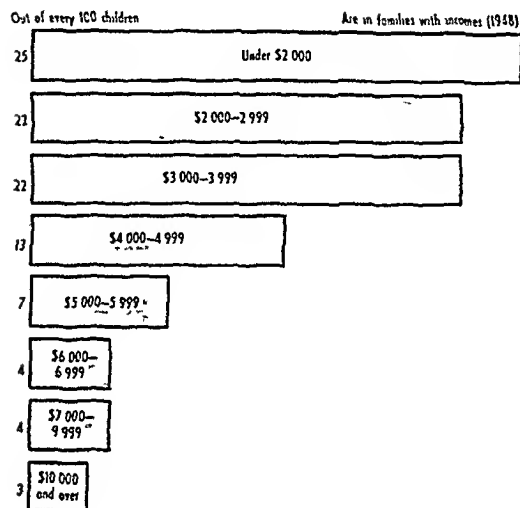

mote from the problems confronting these professions and others interested in making the most of what medicine and public health have to offer. Five important factors deserve discussion. Figures given are derived almost entirely from the 1950 census.

Population Growth. The population is actually growing younger faster than it is growing older. In the last decade, the number of children under 5 years increased 55 percent while persons over 65 years increased only 37 percent. During the next two decades, the number of school-age children and adolescents will increase substantially. This increase in the number of children will necessitate additional child health activities just to provide the same services available today.

Younger Parents. Couples are becoming parents at a younger age today than they did in past generations. One-third of the females in 1950 were under 20 years of age at marriage, and the median age of marriage has declined ever since 1890. Parents are, however, better educated, with some 4 years more schooling than the generations born in 1890. Therefore, though they do not come to child-bearing with many of the specific skills and knowledges formerly acquired in the large families of yes-

Family Size and Income

In 1949, 15 percent of the Nation's 39 million families had 3 or more related children under 18 years—a total of some 23 million, or about half of all children under 18. More than

half of the families with 3 or more children and almost two-thirds of those with 5 or more live on farms or in rural-nonfarm areas. Over two-fifths of the total number of families had no children under 18, some because their children had grown up, some because of recent marriage. About 30 percent of families with related children have 2 children, and about 40 percent have only 1 child under 18 years. The chart at left indicates that most children are in low and moderate income families. Also, most large families have lower incomes than small families.

terday, parents probably can be counted on to do more themselves for their children if shown how.

Economic Status. One-half of the children live in families with three or more children, and about one-half live in families with an income of less than \$60 a week. In general, the larger the family, the smaller the income. Children are concentrated, too, in relatively few families, with 16 percent of all families caring for 61 percent of all children. Because married couples become parents at a younger age than formerly, they earn less in the years when their children are young. These facts lead to the conclusion that most of our future citizens are being brought up in families in which it usually is not possible for the family alone to provide all of the health services advised.

Family Stability. In recent years great stress has been placed on how much the health and stability of the adult depend upon the support of a stable, secure family during his early years. Bowlby (1) has recently reviewed evidence

showing the positive relationship between early maternal care and later mental health. These figures then may be significant: One out of 8 children in the United States lives in a home that does not have 2 parents or does not live in a family at all; 1 out of 5 mothers works away from home; children born out of wedlock have increased 50 percent within the last decade, with a total of 135,000 such births occurring in 1949, 30,000 of these to girls under 17 years of age.

Chances for Survival. The chances for survival and the quantity and quality of medical and dental care received by children vary widely in different parts of the country and in different economic groups. The recent American Academy of Pediatrics study (2) indicates that the child's very chances for survival depend upon where he lives and who his parents are. It shows, too, that doctors, even from good medical schools, have too little opportunity to learn modern pediatrics and that there are definite needs for better distribution of health and medical services and for more and better

professional education at undergraduate and graduate levels.

These are some of the problems of maternal and child health in the United States today. Great progress has been made and significant leads have been obtained as to where to go in the future, but because of the lack of scientific knowledge in certain areas and the uncertainty as to how best to proceed in others, a great deal of uncharted sea lies ahead.

Suggestions for Action

Although the public health program for the future cannot, of course, be laid down in specific terms, the following general suggestions warrant consideration.

Research

A greatly augmented program of research into the problems of human reproduction and the growth and development—physical, mental, and emotional—of children is needed. Such a program requires the development of one or more institutes directed to the study of human beings. An institute of this type should have on its staff research persons from many fields: anatomy, obstetrics, genetics, pediatrics, statistics, embryology, physiology, chemistry, physics, and the social sciences. Among the problems lending themselves to immediate attack are

Successful attacks against many of the "common" childhood diseases have cleared the way for more aggressive approaches to some of the more stubborn problems—cerebral palsy, epilepsy, rheumatic fever, congenital heart defects, poliomyelitis.

the causes of death and malformation at or near birth and the accident problem. The apparent increase of mental illness and maladjustment also indicates further study is needed to verify or disprove the leads which the mental health movement is developing concerning personality growth.

Evaluation

A second point of attack is the development of more critical evaluation studies of ongoing services. Some of the maternal and child health programs are a half century old. Are they still meeting a public health need? If not, they should be terminated. If so, methods used and results obtained should be studied to determine if these programs are as effective as they could be.

Take, for example, school health services. The one study of the past few years that probably has had the greatest influence in this field is the so-called Astoria study (3). It attempted essentially to answer one simple question: "How can the time now spent by teacher, doctor, and nurse in the school be spent more productively?" This question needed answering and the result undoubtedly has increased the efficiency of many school health services. But in

Homemaker services provided in many communities—sometimes under health department auspices—represent an important contribution to family health and child security at times when the mother is ill or temporarily disabled.

Nowhere in the country are there enough foster homes, residential treatment centers for emotionally disturbed children, or other facilities for specialized types of care. The lack is most acute outside metropolitan areas.

the light of the enormous sums spent in school health activities and the changes in the nature of the health problems of today's children, other questions need answering. Is any of the school health service time worth spending? Are there other more effective ways of locating children in need of medical care? And what are the really effective ways of securing care for those who need it? In short, what are the real health needs of today's school children?

To evaluate ongoing services will not be easy. Methods are often still to be developed. There is little tradition for such research, and few investigators are trained for or interested in this approach.

Service Coordination

A third approach is the coordination of current activities for the promotion of the child's health when he is well with those for his care when he is sick or chronically ill. Certainly, the practice of caring for the child in one clinic when he is well and in another when he is sick is not justified administratively nor is it satisfying to the family. All children need sound advice about health care and growth and development as well as specialized care for their particular ailments.

Many of the current child health problems seem to require a team approach—for example, the rehabilitation of the child with cerebral

palsy, a severe hearing loss, or rheumatic fever. Isn't there some way of promoting a closer working relationship between public health personnel and the general practitioner, without whom many of the past achievements could not have been made? Wouldn't it be possible to work out an agreement whereby the general practitioner's patients could be helped by the public health nurse, nutritionist, and similar persons? Certainly, experiments can be made to determine the feasibility of providing, in one geographic location and with as far as practical the same staff, all the health services a particular child needs.

Social Science Approaches

The fourth approach should be an attempt to use more effectively some of the findings of social scientists. They stress, for example, the use of community groups having a common interest in the solving of problems which demand changes in behavior. The therapeutic value of groups such as Alcoholics Anonymous or parents of children with cerebral palsy or diabetes has been demonstrated. Why shouldn't the value of work with groups of parents of 6-month-old or 2-year-old children be tested? Attempts in this direction have been made and seem to confirm the opinion that this type of group approach has great potentialities.

Failure to focus on the whole family in a human kind of way has characterized many of our efforts in the past. The effective care of the child is a complicated process involving, particularly in early years, all the family and more than good physical care. For example, maternity care has often been interpreted as the maintenance of a complicated piece of machinery located in the female pelvis. Certainly this approach has saved thousands of lives. But hasn't something needlessly been lost in the meantime? The birth of a child is a natural function and involves all the members of the family. The recent swing to a more human approach to the expectant mother and the newborn infant in this country should be a matter of rejoicing among all public health workers. A better foundation for family life is thus being built, with no loss in effectiveness of lifesaving measures. Years ago that remarkable experiment at the Peckham Health

Well child care provides an opportunity to promote the emotional as well as the physical health of children. But too few children get health supervision when they are not sick. Children living in the South and in isolated counties get far less care from physicians in private practice than children elsewhere. Children living in metropolitan counties receive one-third of their care from pediatricians and other specialists, but children in isolated counties get very little service of this kind. Less than one-tenth of the well child care is given at clinics, and most clinics are held in metropolitan counties.

Center demonstrated the value of bringing the whole family in on health problems of the individual in the family (4).

Possibilities for Progress

Finally, new ways of bringing to more people the benefits of medicine and public health need to be developed. Part of the picture, as previously pointed out, involves economic problems, but there are other problems too, some relatively simple and solvable today.

For example, why is there such a wide variation in the maternal and neonatal mortality rates and in quantity and quality of maternal and infant care in the same area? Recent studies in one large urban area where well-trained physicians and nurses are found in all hospitals show startling differences in practices (5, 6). With hemorrhage a leading cause of maternal death, is it really interference with the practice of medicine to insist, for example, that all hos-

pitals have blood readily available in the delivery room? Is it too much to require that anesthesia in the delivery room or gavage feeding in the premature nursery be given by persons who have been especially taught the techniques? Hospitals were long ago compelled to eliminate cross connections in plumbing and to drop silver nitrate in the eyes of newborn babies.

Why, despite all the evidence indicating the value of maternal care in early infancy and its relation to mental health in later life, isn't something more concrete done to provide continuity of maternal care for infants? Gains in emotional stability may be made by keeping children in their own homes instead of placing them in institutions. Much greater efforts should be made in this direction. Consider, for example, the commonly accepted practice of private and public agencies of paying more per day for the care of a child in an institution than in a foster boarding home, or the reluctance of these agencies to pay for homemakers or housekeepers to enable parents to keep children in their own homes. Is it practical not to tackle more effectively also the problem of care for the 135,000 children born annually to unwed mothers?

Individual Action

These are but a few examples of approaches to existing problems. Many of the problems await concerted action over a long period of time, and many require action which the individual health worker cannot initiate by himself. But each worker, as he performs his day-to-day tasks, can initiate action directed toward the goals suggested above.

He can, for example, reexamine his current activities to see if he is directing his major efforts toward those which apparently add to the physical, mental, and social well-being of those he serves. He can attempt to look at his daily job from a "new approach," exploring the possibilities of trying out a better way of doing the job or learning what persons of allied professions have to offer. He can add the human touch to his relations with those he serves. He can remain flexible, for the future of child health and public health lies in the ability of its

personnel to remain flexible and creative so that they can adapt new knowledge to old problems.

Children's Bureau Reports 1951 Adoptions

Nearly half the children adopted in 1951 by persons not related to them were placed in adoptive homes without the safeguards that both the children and parents should have, according to the Children's Bureau, U. S. Department of Health, Education, and Welfare. Forty-eight percent of children adopted by nonrelatives were placed into the adoptive home independently of a social agency.

The Children's Bureau report on adoptions in 1951 was prepared from data furnished by State public welfare agencies, on the basis of which the Bureau estimates that probably 80,000 adoption petitions were filed during the year. This is a 60-percent increase over adoption petitions filed in 1944.

The report attributes the increase in adoptions to the large number of homes broken by death, divorce, or desertion during and following World War II, and to the increase in the number of children born out of wedlock.

The average age of the children for whom adoption petitions were filed was 3.3 years in the 25 States reporting substantially complete information for 1951. Two-fifths of the children were under 2 years of age at the time the adoption petition was filed.

In independent placements, more than half of the children were under 1 month of age at the time of placement. This means that many of these children were placed either directly from the hospital or shortly thereafter. Only 11 percent of the children placed by agencies were under 1 month.

In the 25 States reporting complete information on adoption petitions, the number of adoptive children was almost equally divided between those born out of wedlock and those born in wedlock. Non-related persons filed adoption petitions for 69 percent of the adoptive children born out of wedlock but only 25 percent of those born in wedlock.

Cardiovascular Syphilis In a General Medical Clinic

By S. P. LUCIA, M.D., VERNON C. HARP, JR., M.D.,
and M. L. HUNT, M.P.H.

Cardiovascular involvement is one of the more important manifestations of late syphilis, producing marked physical incapacity and a high accidental mortality. Diagnosis is often difficult, which is important, because the type and amount of therapy are dependent upon the degree of cardiovascular involvement.

The study here reported was undertaken to determine the incidence of cardiovascular syphilis in an outpatient department of a general medical clinic, the types of lesions most commonly encountered, and the age groups most frequently affected.

The group studied was made up of 830 patients referred to the Luetic Cardiovascular Clinic by the Clinic of Dermatology and Syphilology, University of California Medical Center. During the 12-year period, 1939-51, 2,273 of the total of 274,782 patients seen at the medical center were referred to the Clinic of Dermatology and Syphilology because they had either a history or serologic tests indicative of syphilis. The 830 patients in this study were in turn referred to the Luetic Cardiovascular Clinic, where 354 were found to have cardiovascular syphilis and 187 were found to have other cardiovascular disease (table 1).

Most of the patients with cardiovascular syphilis (310, or 87.7 percent) were over 40 years old; 213 were in the age group 41-60; 97 were over 61; only 44 were aged 21-40 (table 2). Aneurysm was the most frequently observed lesion in the older age groups, 48.4 and 67 percent, respectively; simple aortitis was found in 47.7 percent of the younger group. It is prob-

able that in the older age groups the syphilitic process has been present longer, thus increasing the possibility of involvement of the heart as well as other organs.

Of the 354 patients with cardiovascular syphilis, 91 (25.7 percent) had simple aortitis; 180 (50.8 percent), aneurysms; 42 (11.9 percent), aortic insufficiency; and 41 (11.6 percent), a combination of aneurysm and aortic insufficiency (table 3).

Diagnosis

In the Luetic Cardiovascular Clinic, the cardiovascular history, results of the physical examination, and conclusions drawn from a fluoroscopic examination, which represented an agreement between the various members of the examining staff, were recorded on a standard form. Examinations of the patients were made at intervals of 3, 6, or 12 months as the situation required. These examinations served as a check on the previous findings and also permitted detection of any progress in the disease process. From the data obtained, the diagnosis of cardiovascular disease was made;

Table 1. Incidence of cardiovascular syphilis in 2,273 patients referred to the Clinic of Dermatology and Syphilology and in 830 patients further referred to the Luetic Cardiovascular Clinic

Type of cardiovascular disease	Patients referred to Luetic Cardiovascular Clinic		Percent of 2,273 patients referred to Dermatology and Syphilology Clinic
	Number	Percent	
Total.....	830	100	36.5
Syphilitic cardiovascular disease.....	354	42.7	15.6
"Other" cardiovascular diseases ¹	187	22.5	8.3
No evidence of cardiovascular disease.....	289	34.8	(²)

¹ Rheumatic heart disease, 7 cases; congenital heart disease, 1 case; arteriosclerosis and hypertension.

² This group represents only that portion of the 830 individuals originally suspected of having involvement of the heart and therefore cannot be statistically evaluated in relation to the total 2,273 patients.

Dr. Lucia is professor of medicine and chairman of the subdepartment of preventive medicine, Dr. Harp is clinical assistant in medicine, and Miss Hunt is a graduate research immunologist at the University of California School of Medicine, San Francisco.

Table 2. Age distribution of 643 seropositive patients, by presence or absence of syphilitic cardiovascular disease

Diagnosis	Total	Age groups				
		Under 40	41-50	51-60	61-70	Over 70
Total.....	643	184	198	158	87	16

No evidence of syphilitic cardiovascular disease.....	289	140	91	52	6	0

opinion as to its activity, severity, and progression was given; and a plan of therapy was recommended.

Recognition of syphilis of the cardiovascular system depends upon the detection of weakness in the walls of the aorta. Chest pain, cough, dyspnea, or hoarseness, a broadened area of dullness at the base of the heart, unilateral pulse weakness, and a tambour quality of the aortic second sound all suggest syphilitic cardiovascular disease. An aortic diastolic murmur is of positive diagnostic significance since it is usually associated with a widened pulse pressure and it may be accompanied by the peripheral signs of aortic insufficiency. Although aortic insufficiency may follow advanced arteriosclerosis, the peripheral signs of aortic insufficiency, in such instances, may be minor or absent.

A fluoroscopic examination is the most reliable method of detecting cardiovascular syphilis in its early stages, and a series of fluoroscopic examinations provides the best indication of the progression and severity of the disease. The earliest positive sign of aortitis is a definite broadening of the ascending aorta. By serial examinations, progressive enlargement, sacculatation, and fusiform dilatation of the aorta are revealed. Fusiform dilatations of the ascending aorta are not invariably due to syphilis, but are more frequent when this disease complicates the usual changes caused by arteriosclerosis and hypertension. Fusiform aneurysms are usually, but not necessarily, due to syphilis, while saccular aneurysms are almost always the result of syphilitic aortitis.

In our experience, calcification in the wall of the ascending aorta is most often consequent to syphilitic invasion; in the wall of the abdominal aorta it is usually the result of arteriosclerosis, and in the thoracic aorta or aortic knob it may be due to arteriosclerosis alone. Calcification occurring exclusively in the ascending aorta indicates that the sclerotic changes are more marked because of the antecedent syphilitic inflammation.

Age Groups Affected

In table 2 the age distribution of 354 individuals who were diagnosed as having cardiovascular syphilis is compared with the age distribution of 289 individuals in whom no evi-

Table 3. Incidence of syphilitic cardiovascular lesions, by age

Lesion	Total		Age (years)						
	Number	Percent	21-30	31-40	41-50	51-60	61-70	71-80	81+
Total.....	354	100.0	7	37	107	106	81	14	2
Simple aortitis ¹	91	25.7	5	16	40	22	7	1	0

Aneurysm and aortic insufficiency.....	41	2	4.6	21	9.8	18	18.5

dence of cardiovascular disease was found. The incidence of syphilitic cardiovascular lesions, by age, is shown in table 3.

Incidence of Lesions

The lesions which were considered to be the result of syphilitic invasion of the cardiovascular system were simple aortitis, aneurysms, aortic insufficiency, and aneurysms and aortic insufficiency combined.

In the group of patients with simple aortitis due to syphilis associated symptoms such as aortic systolic murmurs or a hollow quality to the aortic second sound were also present. There were no instances of aortic insufficiency, aneurysm, hypertension, or gross arteriosclerosis of the aorta in this group. Aneurysms were present in 221 (62.4 percent) of the patients, and in 41 of these the aneurysm was accompanied by aortic insufficiency. On auscultation, insufficiency of the aortic valve was revealed in 83 (23.4 percent) of the patients, and in 42 of these there was no fluoroscopic evidence of an aneurysmal dilatation of the aorta.

Types of Lesions

In table 4 the data are arranged by age groups and according to the character of the lesion. In the light of the present day concept of the pathological changes in syphilitic aortitis, the first assault on the aorta would lead to a simple inflammatory process with broadening of the aorta and advance to the production of

aneurysms with or without involvement of the aortic valve itself. Accordingly, a greater incidence of simple aortitis would be expected in the young subject suffering from syphilitic cardiovascular disease and with increasing years an augmented incidence of aneurysm. A comparison of the incidence of simple aortitis in three age groups (table 4) reveals a statistically significant decrease in the occurrence of simple aortitis with advancing age and a statistically significant increase in the incidence of aneurysms. Aortic insufficiency occurred according

Table 5. Aneurysms of the aorta, by site of the lesion

Location of aneurysm	Number	Percent
Total.....	254	100.0
Ascending aorta.....	211	83.1
Transverse aorta.....	14	5.5
Descending aorta.....	29	11.4

to the statistically expected frequencies in each of the three age groups studied.

Of the 221 patients with aneurysms due to cardiovascular syphilis, several had more than one aneurysm—a total of 254 (table 5). Most of the aneurysms (211) were in the ascending aorta, 29 were in the descending aorta, and 14 in the transverse aorta. Of the patients who had aneurysms of the transverse or descending aorta without involvement of the ascending aorta, 4 were in the age group 41-60, and 6 were in the age group 61-81+.

Conclusions

In the diagnosis of cardiovascular syphilis it is important (a) to make a systematic evaluation of the symptoms and physical signs suggestive of the disease. (b) to subject the patient to serial fluoroscopic examinations to determine the presence or absence of aortitis, and (c) if

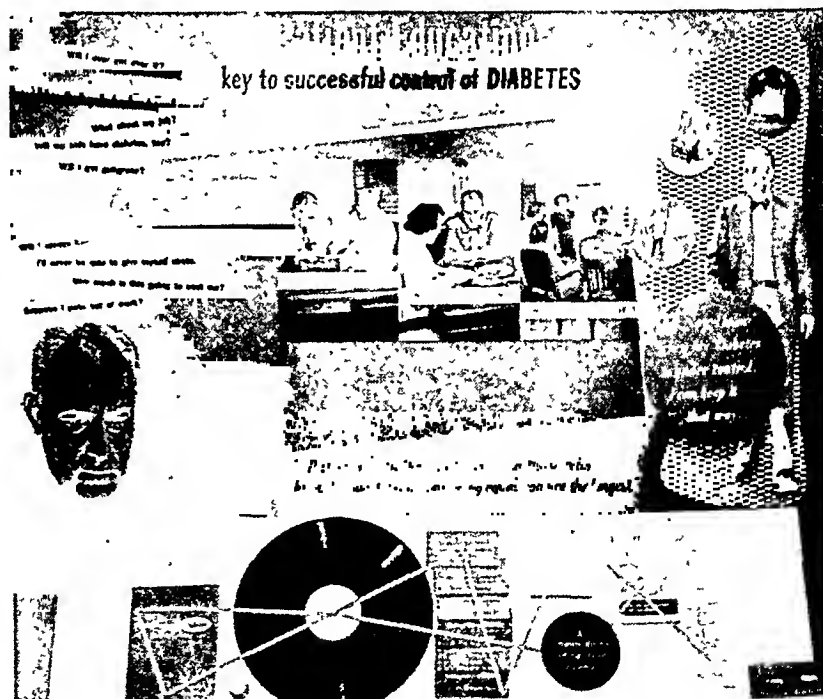

lesions are detected, to assess the rate of progression of the disease. Data obtained from such examinations are of value in deciding whether further therapy might introduce a hazard, especially in the advanced age group where hypertension, arteriosclerosis, and other evidences of degeneration of the cardiovascular system may coexist.

Diabetes Exhibits Available to Professional Groups

"Look for diabetes," is the theme of the Public Health Service exhibit (left) displayed at the 1952 annual meetings of the American Medical Association and District of Columbia Medical Society. The exhibit is 12 feet wide and 5 feet deep and weighs 250 pounds.

"Patient education, key to successful control of diabetes," (right), a Public Health Service exhibit, depicts control measures for diabetes. The lower panel displays some components of a kit of filmstrips, records, posters, and pamphlets which may be used by clinics, professional personnel, and public health workers for teaching diabetic patients. (Inquiries on how to obtain the kit separately from the exhibit should be addressed to your State health department.) The exhibit was first shown at the New England Health Institute, Storrs, Conn., and then at the annual meeting of the American Diabetic Association in Minneapolis in 1952. The exhibit is 6 feet wide and weighs 250 pounds.

Official agencies and voluntary organizations may borrow these exhibits for showings to professional audiences. The borrower, however, must pay the cost of transportation and insurance, both ways. Inquiries concerning the availability of the exhibits should be addressed to the Division of Chronic Disease and Tuberculosis, Public Health Service, Washington 25, D. C.

Public Health in Indonesia

By E. ROSS JENNEY, M.D., M.P.H.

IN THE NEW NATION of Indonesia, the principles of sound public health practice are being cross-examined and evaluated in relation to some of the most involved problems to be considered by one nation at one time. It is fascinating to observe, for some astute minds are being challenged to find a practical answer to what becomes, as one lives with it, a complex of conundrums. Most of the Indonesian officials who are responsible for making decisions have a local background plus an education in Western medicine and public health methods. This fortunate circumstance insures a realistic compromise with nicely budgeted programs nurtured in lands of economic affluence, but at the same time provides a dissatisfaction with the slow development of preventive medicine in the East.

A Nation of Islands

Although the Republic of Indonesia is but one of several nations born from the partial collapse of colonialism in Asia, its problems and advantages are such as to place it in a rather unique position in regard to future planning, particularly in public health. The nation

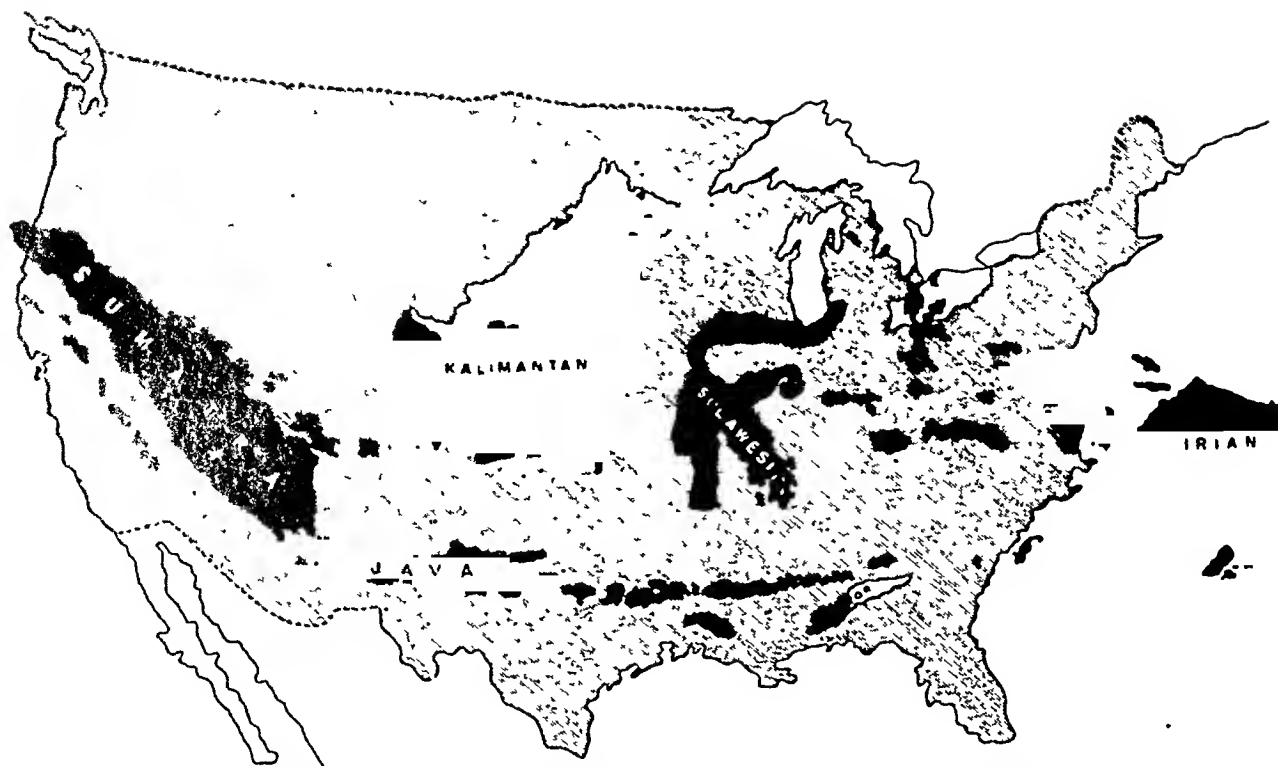

holds sovereignty over the former Netherlands East Indies, comprising Sumatra, Java, Borneo, Celebes, some 25 smaller satellites which except for Bali and Ambon are scarcely known to the world by name, and 13,000 interspersed small islands of which 2,600 are populated. Jurisdiction of the western half of New Guinea (Irian) is in dispute. Indonesia is, then, a nation composed solely of the world's largest archipelago with a land area of 750,000 square miles stretching across an equatorial area of 3,500 by 1,500 miles. If the northern tip of Sumatra were at New York, New Guinea would lie across North Africa.

Population Characteristics

Living on these islands is an unevenly distributed population of about 75 million. Java, with 52 million people and 51,030 square miles, has 70 percent of the population and only 7 percent of the land area. This is equivalent to one-third of the population of the United States living in the State of Florida. Density of population in Java averages over 1,000 per square mile. Since much of the island contains the sloping terrain of 50 volcanoes, the population density per square mile in some areas is approximately 1,700—the greatest rural population density in the world. In contrast to this, Borneo, the third largest island in the world, has a population density of about 14 per square mile.

The inhabitants of Indonesia are of Malay descent. The Chinese merchant is everywhere and with the Europeans, Arabs, and Indians forms a minority population of perhaps 2,500,000. Although many languages are used, comprising over 200 dialects, the language is being unified by promulgating "Bahasa Indonesia,"

Dr. Jenney has returned to Washington, D. C., from a 2½-year assignment as chief of the public health division of the Technical Cooperation Administration Mission to Indonesia. Before entering the Public Health Service as a commissioned officer in 1949, he served as chief of public health of military government in Bavaria (1946-48) and chief of public health, Allied Mission to Norway (1944-45). His earlier career included an assignment to Labrador with Sir Wilfred Grenfell's mission.

Indonesia superimposed on the United States. The Republic of Indonesia, lying between the land masses of Asia and Australia, is a nation composed solely of the world's largest archipelago stretching across an equatorial area of 3,500 by 1,500 miles.

which is similar to the variety of Malay spoken in the Riouw Archipelago near Singapore. The religions of the Indonesians are derived from the Hindu kingdoms of the seventh and eighth centuries and the Mohammedan infusion in the thirteenth and fourteenth centuries. Hinduism survives in Bali, but over 90 percent of the Indonesians are Moslem. The areas not strongly Moslem at the arrival of the Europeans have been more susceptible to conversion to Christianity, notably the island of Ambon, the northern tip of Celebes, and the area around Lake Toba and Medan in Sumatra.

Climate

Although the climate of the river bottom lands is tropical in every sense, the mountains, which rise to peaks commonly 10 to 12 thousand feet, provide a range of climate that is quite agreeable. The coastal cities of Java have a climate comparable to our own eastern cities in summer, and a blanket at nighttime is usually needed in the mountain towns.

Except for the more arid Lesser Sunda

Islands, the entire archipelago is carpeted in tropical vegetation, from the coastal swamp lands to the slopes of the volcanoes. In Java, this has given way to agriculture, chiefly in the form of the famous terracing for the rice paddies, and to the agricultural plantations of the Dutch.

Exports

Although the 3½ years of Japanese occupation, subsequent military actions, and other factors have compromised the export situation, before World War II Indonesia provided 37 percent of the total world's export of rubber, 19 percent of tea, 27 percent of copra, 24 percent of palm oil, 91 percent of quinine, 86 percent of pepper, 72 percent of kapok, 25 percent of hard cordage fibers, 3 percent of petroleum, 17 percent of tin, 5 percent of sugar, and 4 percent of coffee. Of the total export value, 30 percent was in rubber, 21 percent in petroleum, 13 percent in copra and palm oil, 11 percent in tin, and the balance in sugar, tea, and other products.

The exports in 1950 in order of importance

were rubber, petroleum, tin ore, copra, tobacco, tea, and palm oil. The chief consumer countries were the Netherlands, the United States, Singapore, the United Kingdom, Germany, Japan, and Australia.

In contrast to its extraordinary beauty and its potential wealth, Indonesia carries a heavy burden of poverty, ignorance, and disease. The individual subsistence level farmer dominates the agricultural pattern, and the rapid increase in population implies a questionable future for Java. Literacy is estimated at 17 percent. Since this is largely in the urban areas, the rural population of 65 million is nearly illiterate.

The Health of 75 Million

Studies predicated upon limited surveys indicate a birth rate of 28 and a death rate of 20 to 25 per 1,000 a year. Maternal mortality is estimated to be in the neighborhood of 16 per 1,000 live births, and infant mortality varies from 115 to 300 per 1,000 live births a year but has been shown to be higher in some areas. Life expectancy scarcely can be guessed, but the figure of 32 years is commonly used.

Javanese returning from market. Human excreta is disposed of almost exclusively in the sluggish canal ("kali") on the right, which is also used for bathing and for washing vegetables and clothes. Indonesians, who have a highly developed sense of personal cleanliness, have been slow to appreciate the values of modern sanitation.

Associated with the Medical School (above) of the University of Indonesia in Djakarta (Java) is a modern 1,200-bed general hospital. At this school, one of the three medical schools in Indonesia, 25 students were graduated in 1951.

Malaria

Indonesia is one of the world's great endemic areas of malaria. Carried by both fresh and salt water *Anopheles* which breed throughout the year, the disease is common almost everywhere in the archipelago. In coastal areas, where incidence is apt to be high, the spleen index is frequently 90 percent or more. The incidence by attacks for each year, as in most of Southeast Asia, is estimated at 30 percent, and the annual mortality ranges from 20 to 40 per 1,000 in endemic areas of high incidence. In severe epidemics, records have shown 40 percent of the afflicted population dying from malaria within a year. Malaria certainly causes more deaths in Indonesia than any other disease and has a profound effect upon the economy of the country and upon mortality from diseases with which it occurs concurrently. Tertian and estivo-autumnal forms of the disease are in about equal proportions, with scattered areas of quartan forms in the Lesser Sunda Islands.

Tuberculosis

As in most tropical areas, tuberculosis is impossible to evaluate in statistical terms. There are at least half a million open cases, and it is known to constitute a major cause of death, perhaps 8 to 10 percent of the total. Limited surveys have shown the mortality rate to be 189 per 100,000 a year, but it is probably much

higher. There can be no doubt that a postwar increase in the disease occurred and that it will be many years before a quantitatively adequate approach to the problem can be devised. In the meantime, living conditions are contributing to the spread of tuberculosis, and it will probably emerge as the most difficult of all health problems.

Other Diseases

Typhoid fever, the paratyphoids, both bacillary and amebic dysenteries and the common diarrheas are extremely widespread throughout Indonesia. War damage and the increase in population contribute to their spread in rural areas, and recent overcrowding severely taxes urban sanitary facilities.

Yaws is found in proportions ranging from 5 percent to 90 percent and averages perhaps 15 percent; it is probable that there are 12 or 15 million cases. It is generally conceded that half of the world's cases of yaws are in Indonesia.

Filariasis has a variable incidence in different islands. It is particularly prevalent on the east coast of Sumatra, in Banka, in the Moluccas, and in the two southern peninsulas of Celebes.

Tropical typhus occurs in most of the islands except Java, and dengue is everywhere. Pneumonia is a common cause of death, particularly in infants. There is an occasional threat of cholera, but the disease must be considered eradicated. After very extensive control measures, plague now appears only sporadically, chiefly in mountain areas of Java. However, as recently as the first half of 1951, there were 2,861 cases and 1,185 deaths reported in Java and Madura. Smallpox has been nearly eradicated at various times but occurs at intervals by reintroduction. Following World War II there were widespread epidemics because the previous extensive vaccination program lapsed during the Japanese occupation. A recent introduction of smallpox from Singapore was traced from Sumatra to Java where it rose to epidemic proportions in West Java in 1948 and resulted in a severe epidemic in 1950 and 1951 in Surabaya. After spreading through eastern Java and Bali and reaching nearby Madura, it was carried by the Madurese fishermen to west and

south Borneo and from there to the Gulf of Bone in Celebes and to Ambon.

Leprosy, trachoma, and leptospirosis are all widespread, with an incidence corresponding to that found in most tropical countries. There are about 70,000 lepers in the nation. Rabies is common among dogs, in West Java particularly. Tetanus neonatorum is a frequent cause of infant mortality, especially in Celebes. Scabies is almost universal with frequent secondary infections. Tropical ulcers, tinea infections, and other tropical skin diseases are everywhere. Hookworm is widespread in the population, with perhaps a 50-percent prevalence in much of Java and 80 percent in the northern and southern peninsulas of Celebes. *Ascaris* infestation is almost universal, and other forms of helminthiasis abound. The rural prevalence of venereal disease is unknown, but there are indications that it affects not less than 10 percent to 20 percent of the population in urban areas.

Indonesia shares with the rest of Asia the unexplained freedom from yellow fever in the presence of the mosquito vector. Leishmaniasis is rarely encountered and is always imported, and schistosomiasis has been found only in a limited area of central Celebes at the base of the northern peninsula.

Malnutrition

The actual degree of malnutrition is relative matter in the tropics and is difficult to evaluate. Indications are that most of the inhabitants are living in a borderline state of malnutrition in regard to vitamins, protein, calcium, cholesterol, and iodine. Clinical cases of nutritional deficiency are observed to some degree everywhere and in a high degree in certain areas, particularly in conjunction with postmalarial anemia. Endemic goiter is frequently seen in the mountains of Sumatra, Celebes, Bali, and elsewhere, and edema caused by lack of protein is not uncommon.

Of the vitamin deficiencies, the lack of vitamin A is by far the most predominant, contributing to much eye infection and subsequent blindness. Kidney and bladder stones, possibly connected with a lack of vitamin A, are common, and in some hospitals 10 percent of all pediatric surgery is for this condition.

The Ministry of Health of the Republic of Indonesia is responsible for almost all medical and public health services in the nation. It is a highly centralized system working toward decentralization. It has assumed the functions of the former Netherlands East Indies Public Health Services, operates and staffs government hospitals and polyclinics, and controls most of the distribution of medical supplies and equipment. The present organization of the ministry dates from August 17, 1950. Earlier, there was a separate ministry of health at Djogjakarta.

Before the war, there were 207 general hospitals in Java and Madura, with a capacity of 19,022 beds (0.39 beds per 1,000 population). In addition, there were privately owned hospitals, missionary hospitals, and the medical facilities of plantations, petroleum companies, and so forth.

The Ministry of Health reports that in all of Indonesia there are now 600 general hospitals with 55,000 beds and 78 special hospitals and sanatoriums with 11,204 beds. The government owns about 35 percent of all hospital space, but a large part of the remainder is under some form of subsidy.

In 1942, there were 1,700 polyclinics operated by the Netherlands East Indies Public Health Service of which only 500 were in continuous daily use. Only the most important of these clinics were visited daily by a physician. The remainder were usually staffed by specially trained male nurses known as mantris, who frequently were not able to visit each clinic more than once a week. A polyclinic is usually in a small building in the jungle or a room in some community building. Industrial companies, plantations, and estates were charged by law with the care of their laborers. Hence, a close collaboration now exists between the Ministry of Health and these companies.

Before the war the number of physicians was 1,600. Owing to the exodus of many Dutch physicians, there are now fewer than 1,400 physicians in Indonesia, and perhaps no more than 1,000 are actually practicing medicine. This gives a ratio of 1 practicing physician to 75,000 population, which is undoubtedly one of the

Market scene in Bali. The island lies east of Java in the Lesser Sunda Islands, which include Lombok, Sumba, Sumbawa, Flores, and Timor. Population density on Bali averages about 600 per square mile.

lowest in the civilized world. Because of the urban concentration of physicians, the rural ratio is often one physician to several hundred thousand population. No less than 20 percent of the nation's physicians are in Djakarta. An offer of government contract service has recently brought a number of European doctors to Indonesia.

Medical Schools

There are three medical schools in Indonesia. The medical school at Djakarta was founded in 1851. The medical school at Surabaya

was founded in 1913. The medical school at Djogjakarta was founded in 1915. The first two are definitely class A institutions by European standards except for the unfortunate loss of faculty and some destruction and looting of equipment during the Japanese occupation. The institution at Djogjakarta is functioning under handicaps but is not compromising its objective of high standards. A fourth medical school is being planned under local auspices at Medan, Sumatra. There are indications that the medical courses may be reduced from 7 to 5 years.

The combined output in 1951 of the 3 existing medical schools was 25 graduates from Djakarta, 3 from Surabaya, and 2 from Djogjakarta, or 30 in all. There is a low government stipend for some students who must then enter government service for a stipulated period. Since many graduates are destined for private practice, and since the government service has little to offer in remuneration, it is difficult to obtain medical personnel for government service. A physician beginning in government service has a starting salary of 280 rupiah (\$25) a month, about the equivalent of the wages of a railway porter. Even a poor physician can make 10 times that much in private practice. Combining private practice with government service is therefore inevitable for the majority of physicians. This is facilitated by the fact that official government working hours are from 7 a. m. to 2 p. m.

The famous Eijkman Institute and the associated Institutes of Nutrition and Malaria are directly under the Ministry of Health. It was at the Eijkman Institute that vitamin B₁ was first isolated in its chemically pure form by Jansen and Donath in 1926. The Institute of Malaria has two branches with good laboratories in Surabaya and Makassar and a third branch under way in Djogjakarta.

Situated in most of the larger cities are central diagnostic laboratories which operate as branches of the Central Laboratory of Djakarta. Vaccines, including the "living" plague vaccine and the famous dried smallpox vaccine of Otten, are produced at the Pasteur Institute in Bandung. All the medical educational institutions are under the Ministry of Education.

Public Health Organization

The Netherlands East Indies Public Health Service supplanted the former Civil Medical Service in 1925 and was a full-time central public health service with headquarters at Batavia (now Djakarta). Its program was a centralized one until 1934 when provincial health services were organized in Java, Sumatra, and the East Archipelago, under central supervision. By 1937, local health departments had charge of soil sanitation, water supply, sewerage, hospital care, and dispensaries. Decentralization was completed by 1938, and general public health work was also transferred to local authorities and municipalities, an organizational structure which now continues under the central authority of the Ministry of Health.

A large proportion of medical personnel are now employed by the Ministry of Health and the provincial health organizations. In 1937, 651 of 1,135 practicing physicians were employed by the government, and in 1938, 527 of 1,247 physicians.

At the end of 1951, 614 of the slightly more than 1,000 physicians practicing in Indonesia were in government service. The roster of medical and associated medical personnel included:

Physicians.....	614
Pharmacists.....	6
Assistant pharmacists.....	600
Dentists.....	34
Sanitary engineers.....	3
Chemists.....	3
Sanitary inspectors.....	10
Analysts.....	30
Nurses.....	3,500
Midwives.....	1,466
Malaria mantris.....	296
Laboratory technicians.....	226
Plague mantris and technicians.....	407
Vaccinator mantris.....	600
Health education mantris.....	300
Home visitors.....	12

The budget of the Ministry of Health, which covers most of the medical service and all of the public health service, was 5.2 percent of the national budget for 1951 or 6 rupiah per capita per annum, the equivalent of approximately 50 cents.

In general, it can be seen that the public

health problems are widespread and profound, complicated by great distances, poor communications, illiteracy, and poverty. The population, thinly spread in most areas but highly concentrated in Java, is increasing so rapidly that efforts to improve the standard of living scarcely can keep abreast of the increment. Sometimes the situation appears hopeless, but the potential wealth and delightful terrain of Indonesia plus the willingness and natural desire for a democratic way of life and general

temperament of the Indonesians themselves combine to present an inspiring challenge to make these thousands of islands one of the bright spots in this world. The exasperating contrast between what is and what could be—the obvious unreasonableness of it—places a tremendous burden of proof upon all the precepts of planning for human welfare.

NOTE. The photographs and map are supplied through the courtesy of the information division of the Embassy of Indonesia.

Heart Disease Screening in X-ray Surveys

Although chest X-ray surveys search primarily for undiscovered tuberculosis, any suspicious shadow on the photofluorogram deserves special attention, and film readers will uncover many unsuspected neoplasms and cardiovascular abnormalities. Through the years, it has been found that a significant number of persons with nontuberculous chest disease can be discovered in this way—an “extra dividend” of the tuberculosis survey.

The Lung Cancer Committee of the American Cancer Society, at its September 1952 conference in New Hampshire, recommended that the Society cooperate with other voluntary and official agencies in the conduct of X-ray screening programs.

The American Heart Association, the National Tuberculosis Association, and the Public Health Service urge also that every chest X-ray campaign be used to its full potential for heart disease case finding. To this end, the three organizations recently issued the following public statement:

“1. Local voluntary and official health and medical agencies should be urged to accept the responsibility for setting up procedures for referral for diagnostic follow-up and supervision of those cases of suspected heart disease that are found incidentally in the course of reading mass chest X-ray survey films for tuberculosis by

those qualified to read films for tuberculosis but without particular qualifications for reading for abnormal heart shadows.

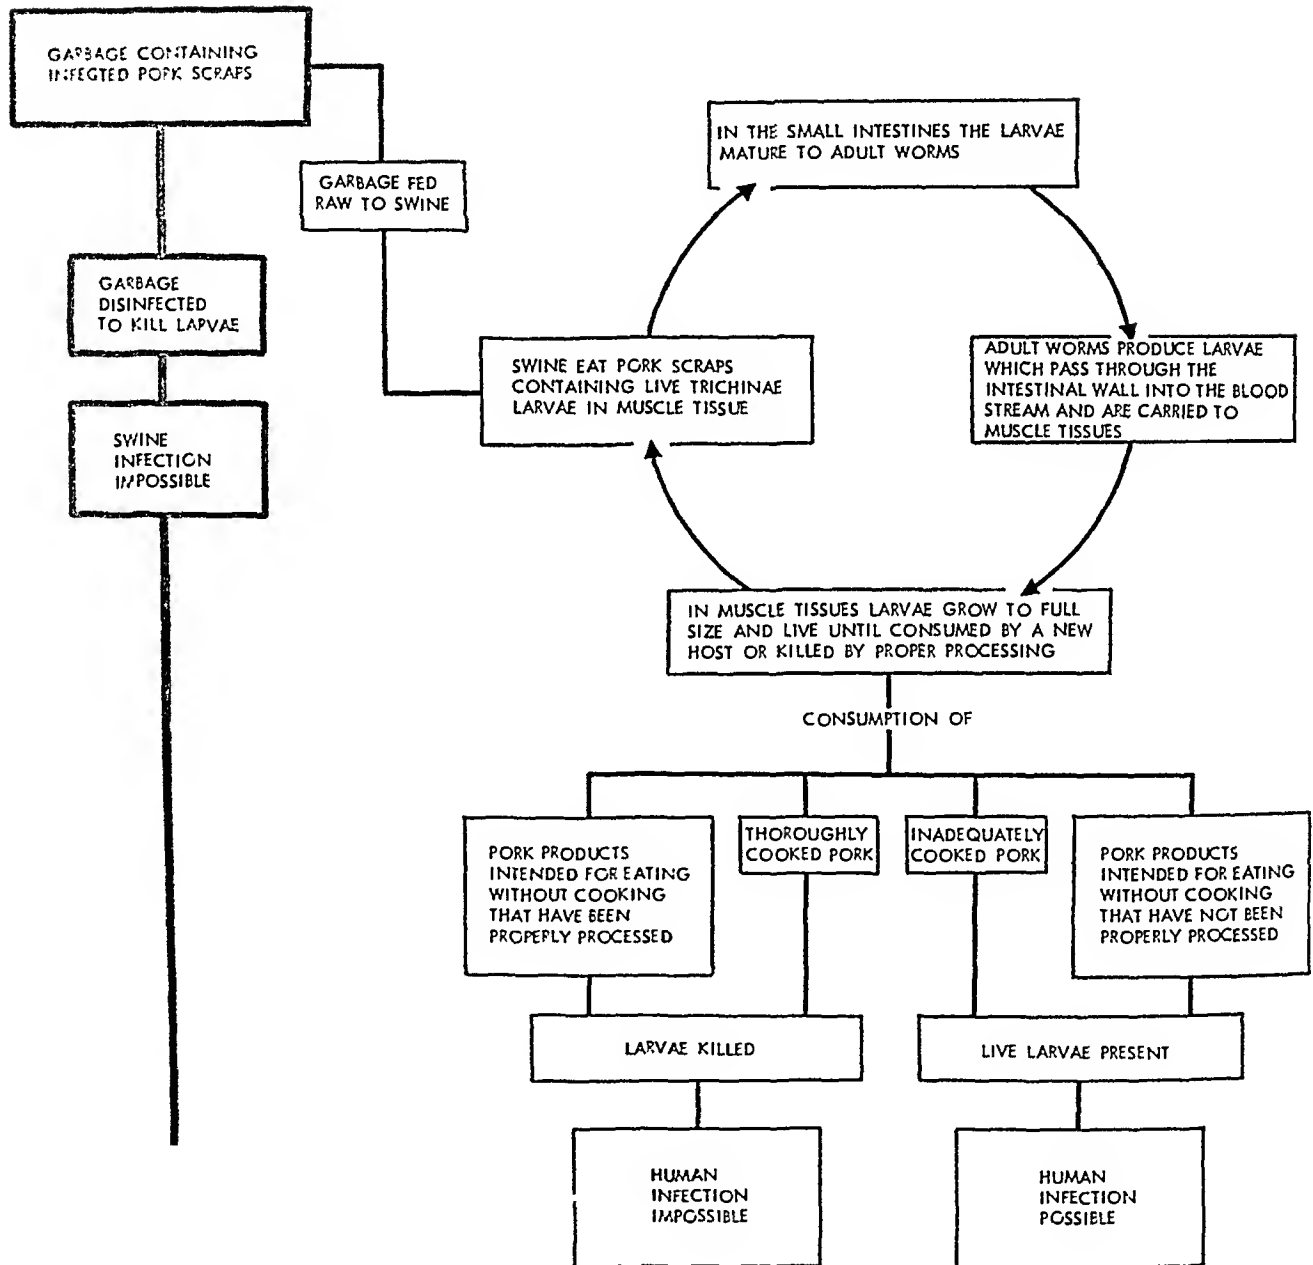

“2. Facts accumulated to date do not justify, at present, a general recommendation to local voluntary and official agencies that any additional procedures (readings by cardiologists, recording of such items as height and weight, and self-completed history form) over and above those outlined in the preceding paragraph be added to mass chest X-ray screening programs in order to raise the level of case finding for heart disease, except on a special study basis.”

The practices of many communities have long been in accord with these principles, and the joint statement represents a crystallization of the experience of these communities.

No single satisfactory screening test, or combination of tests, has as yet been developed which could be justified solely as a way to detect heart disease before obvious signs and symptoms appear. That is why the epidemiological study now in progress at Framingham, Mass., under the auspices of the National Heart Institute includes “an appraisal of the value and efficiency of various methods and procedures for diagnosing heart disease.” As the Institute further points out: “This may lead to a simple way of quickly screening people to detect those who have heart disease.” In the meantime, however, community-wide chest X-ray surveys remain an opportunity for cardiovascular case finding that should not be overlooked.

From the Division of Chronic Disease and Tuberculosis, Public Health Service.

Trichinosis

Human Trichinosis: Transmission and Control

Prevalence • Transmission • Prevention

Highlights from the First National Conference on Trichinosis, 1952

The problem of trichinosis in the United States was reexamined at the First National Conference on Trichinosis, held at the American Medical Association's headquarters in Chicago on December 15, 1952. Sponsoring the conference were the American Board of Veterinary Public Health, the American Medical Association, the American Society of Clinical Pathologists, the American Veterinary Medical Association, the Association of State and Territorial Health Officers, the Conference of Public Health Veterinarians, the Michigan-Memorial Phoenix Project of the University of Michigan, and the Public Health Service.

Topics considered by the conference included the prevalence of trichinosis in man and in swine, principal clinical features of the disease in man, relation of garbage to swine diseases, regulation of garbage-feeding practices, the Federal meat inspection program, the effects of rapid-freezing temperatures and of ionizing radiation on trichinae in pork, and State problems in the control of garbage-borne swine diseases.

The précis appearing here of eight of the conference discussions were prepared by the discussants. The essential points of a ninth, by Ralph J. Van Derwerker of the Public Health Service, are included in the paper presented on page 421. Duplicated copies of the complete papers and of the recommendations adopted by the conference may be obtained from the Secretary of the First National Trichinosis Conference, c/o Veterinary Public Health Section, Epidemiology Branch, Communicable Disease Center, Public Health Service, Atlanta 5, Ga.

A Health and Economic Problem

Trichinosis is a disease of animals, particularly of swine, which affects man when raw or improperly cooked pork containing viable trichinae is eaten. Trichinosis has been shown to have an almost worldwide distribution. It is most prevalent in countries where pork is often consumed raw and least prevalent in Jewish and Mohammedan areas.

Hall and his associates have published a series

of papers concerning examination for trichinae of human diaphragms obtained at autopsy. Of 5,313 diaphragms, 855 showed evidence of trichinae. It is estimated that 1 out of 6 persons in the United States, or about 25,000,000, alive today probably harbor trichinae. To reach this total, there would have to be 350,000 new infections each year. If the conservative figure of 51 larvae or more per gram of diaphragm muscle is used as an arbitrary threshold for producing symptoms, 4.5 percent of

all persons infected, or about 16,000, should exhibit clinical symptoms. This estimate far exceeds the annual average of 336 cases (1942 through 1951) reported in this country. The difference is probably due to inadequate reporting, mildness of symptoms, and the difficulties of making a clinical diagnosis.

It is estimated that of the 60,000,000 hogs slaughtered yearly, 1.5 percent, or 950,000, are infected with trichinae. Although only 40 percent of the trichinosis in hogs can be blamed on those hogs fed entirely on raw garbage, a majority of the remaining 60 percent must be attributed to those fed partly on raw garbage.

Trichinosis is a national problem not only of public health concern, but of economic importance to producers of pork.

—VERNON B. LINK, M.D., *deputy officer in charge of the Communicable Disease Center, Public Health Service*

Garbage-Borne Swine Diseases

Garbage serves as an excellent vehicle for transmission of viral, bacterial, and parasitic diseases in swine. Hog cholera, vesicular exanthema, foot-and-mouth disease, salmonellosis, tuberculosis, brucellosis, and trichinosis are all transmitted in garbage. Hog cholera is the most important porcine disease in the United States, but fortunately this disease is not transmitted to other animals or to man. Vesicular exanthema produces heavy losses among hogs, the only animals that are naturally susceptible to this disease. Foot-and-mouth disease affects not only hogs, but also other cloven-footed animals. Trichinosis affects swine and at least 25 other species of animals. Its chief economic importance lies in the danger of its transmission to man.

All four of these important diseases of swine are associated with the feeding of raw garbage. Their control, therefore, depends upon elimination of this practice. Uniform State and Federal regulations are needed for control of garbage feeding.

Canada and Great Britain have had success in controlling these diseases by requiring that garbage which is fed to swine must be cooked.

Atlanta, Ga., has found incineration to be the most efficient and economical method of disposing of garbage.

—JAMES H. STEELE, D.V.M., M.P.H., *chief of the veterinary public health section, epidemiology branch, Communicable Disease Center, Public Health Service.*

Trichinae in Swine

Of the many mammalian hosts of *Trichinella spiralis*, only the domestic hog is of importance from the standpoint of human health. There is reason to believe, however, that domestic swine in the United States were once infected with trichinae to a much greater extent and to a significantly greater degree than at present.

In the 1930's nearly 1 percent of farm-raised hogs and about 10 percent of garbage-fed hogs in the Atlantic seaboard States harbored trichinae. At least two-thirds of the infected farm-raised hogs contained the parasites in numbers so small that they would undoubtedly have escaped detection by routine microscopic inspection, whereas only about one-third of the infected garbage-fed hogs contained parasites in such small numbers.

In a recent study of more than 3,000 hogs originating in several corn-belt States, trichinae were found in only 0.6 percent when the examinations were made by digesting the pillars of the diaphragm in acidified pepsin. Trichinae were not found in any of these infected diaphragms when they were examined routinely in press preparations, showing that the infections were very light. In parallel studies of a series of about 1,500 samples from garbage-fed hogs on the eastern seaboard, trichinae were found in 11.5 percent when the samples were examined by the digestion method and in nearly 5 percent when examined routinely in press preparations. These data re-emphasize the role of garbage feed in the transmission of trichinae to hogs and to human beings who eat the infected meat raw, inadequately cooked, or imperfectly cured.

—BENJAMIN SCHWARTZ, M.D., *chief of the zoology division, Bureau of Animal Industry, U. S. Department of Agriculture*

Prevalence and Prevention

In autopsy surveys of over 10,000 persons in the United States, the average incidence of recovery of trichinae larvae was 16 percent. However, it has been demonstrated that with more thorough methods of examination the incidence of recovery is about 30 percent. Available data indicate that the incidence of trichinosis in both man and swine in the United States is the highest of any country in the world. The vast majority of human infections are mild and subclinical; most infections that are severe enough to reach the clinical level are not diagnosed; and among those that are clinically diagnosed, the mortality rate is about 5 percent.

Besides thorough cooking, the methods of prevention include curing and low-temperature treatment of pork as prescribed by Federal regulations. Other control measures adopted by some countries include microscopic inspection of muscle from every hog that is slaughtered, prevention of feeding of garbage to hogs, or cooking of raw garbage if it is to be fed to hogs. Promising new methods of rendering pork free from the danger of trichinosis include extension of techniques for low-temperature treatment and exposure of all raw pork to ionizing radiation. These new methods should be subjected to further intensive research. High hope is held that in the near future all raw pork may be so processed as to reduce the danger of trichinosis to man to a point of practical insignificance in this country.

—S. E. GOULD, M.D., *pathologist, Wayne County General Hospital, and clinical professor of pathology, Wayne University College of Medicine*

Federal Meat Inspection

The method of control of trichinosis currently employed by the Federal meat inspection service of the U. S. Department of Agriculture contemplates special treatment under inspection supervision of all pork products customarily eaten without cooking. The so-called microscopic examination was used between 1890 and 1906, but only on export pork. Since 1906 no

microscopic examinations have been made of any pork coming under the Federal meat-inspection program.

Under the Federal program, almost all processed pork products are classed as pork products customarily eaten without cooking. The exceptions include bacon, fresh pork sausage and similar breakfast sausage, and hams and pork shoulder cuts that have been cured but not smoked or otherwise processed. Fresh pork cuts, such as chops and roasts, are not classed as pork products customarily eaten without cooking.

Thoroughly tested heating, refrigerating, or curing processes are prescribed and used in federally inspected meat-packing plants for treating the specified pork products. An extensive survey made recently found that the products so treated were safe without exception. Only dead trichinae were found, and these only in a comparatively small number of cases.

—A. R. MILLER, D.V.M., *chief of the Federal meat inspection service, Bureau of Animal Industry, U. S. Department of Agriculture*

Low-Temperature Treatment

Although data on the effects of rapid-freezing temperatures on trichinae are thus far limited, recent studies indicate that pork may be made safe against trichinosis by (1) rapidly lowering its temperature to -35°C . or (2) by an initial rapid lowering of its temperature to -18°C . and subsequent storage for 3 days at this temperature. Thus, only a few hours may be required to make pork safe by a rapid-freezing method instead of up to 20 days as prescribed under present Federal regulations.

The practicability and the desirability of adopting a rapid-freezing method to make all pork, both that intended for interstate shipment and that for local sale, free from infective trichinae are considered.

—DONALD L. AUGUSTINE, Ph.D., *professor of tropical public health, Harvard University*

Effect of Ionizing Radiation

Ionizing radiations, such as X-rays, gamma rays, and high energy electrons, have been

shown to be effective in killing or interfering with normal development of living material. During the past year the effect of radiation on the life cycle of the causative agent of trichinosis (*Trichinella spiralis*) has been studied.

It has been found that about 1,000,000 roentgens of 200 kv. X-rays are necessary to kill all trichina larvae irradiated in vitro. The killing dose of cobalt-60 gamma rays (1.17 and 1.31 Mev.) was found to be about the same.

However, the life cycle of trichina requires that the ingested larvae grow to maturity in the host and then reproduce. It has been found that radiation doses much smaller than killing doses are sufficient to inhibit maturation and that still smaller doses will sterilize the female trichinae and prevent reproduction. With cobalt-60 gamma rays, about 10,000 roentgens will sterilize all the female larvae in rat muscle, as shown by microscopic examination of the adult female forms recovered from the intestinal tract at 6 days and larval forms recovered from the muscle of the test animals at 30 days. Somewhat lower than killing levels of 200 kv. X-rays are equally effective.

Because of the great penetrating power of cobalt-60 radiation, it is believed that large sections of meat such as hog carcasses could, under suitable conditions, be irradiated as a whole, thus providing a direct method of breaking the trichina cycle.

—HENRY J. GOMBERG, Ph.D., *assistant director, Michigan-Memorial Phoenix Project, and research associate, Atomic Energy Commission Laboratory, University of Michigan;* and S. E. GOULD, M.D., *pathologist, Wayne County General Hospital, and research associate, Atomic Energy Commission Laboratory*

State Problems in Control

The continued practice of feeding raw garbage to only a small portion of the swine marketed in the United States is jeopardizing the entire livestock industry of the country. This practice spreads trichinosis, cholera, vesicular exanthema, and even foot-and-mouth disease.

Practices of hog raising vary in different sections of the United States, and the problems of garbage-borne diseases vary with different States and sections of the country. The two main points to consider in controls affecting garbage-borne diseases of hogs are these: (1) Is the State an exporter or importer of hogs and pork? (2) Is the State an exporter or importer of garbage?

Present interstate and State regulations designed to prevent garbage-borne diseases of hogs are ineffectual. Regulations addressed solely to the movement of raw garbage interstate are not sufficient to handle the problems of the States in controlling garbage-borne diseases of swine. Controls must consider garbage, hogs, and pork. The following regulations are recommended: (1) Prevent the interstate movement of raw garbage except under certain specified conditions; (2) prohibit movement of live hogs and pork out of any State which shall fail to have and enforce regulations requiring the cooking of garbage that is fed to hogs.

The success of any individual State's efforts to control these animal diseases rests squarely on the effectiveness of interstate controls.

—OSCAR SUSSMAN, D.V.M., *chief of the bureau of veterinary public health, division of environmental sanitation, New Jersey State Department of Health*

Trichinosis Control and Vesicular Exanthema

By JACK C. HALDEMAN, M.D., M.P.H., JAMES H. STEELE, D.V.M., M.P.H.,
and RALPH J. VAN DERWERKER, B.S.

TRICHINOSIS, a parasitic disease of animals and man, is a public health problem in the United States. Apparently, it is more serious here than in any other country in the world.

The evidence upon which these statements are based has been in the literature for over a decade and a half (1-3). Although there is still no known specific treatment for this disease in either man or animals, there are practicable preventive measures. Yet in the United States relatively little has been accomplished in the application of these measures and in the breaking of the trichinosis cycle, with the exception of Federal meat inspection procedures to control the processing of pork to be eaten without cooking.

In the late 1930's and early 1940's, studies by Gould (4), Hall (3), Sawitz (5), and Wright (6) indicated that 1 out of every 6 persons in the United States was infected to some extent with the parasite *Trichinella spiralis*.

Dr. Halldeman, from 1948 to 1951 medical director of the Arctic Health Research Center of the Public Health Service, is assistant chief of the Bureau of State Services. Dr. Steele, chief of the veterinary public health section of the epidemiology branch, Communicable Disease Center, Public Health Service, and veterinary consultant for the Bureau of State Services, was the secretary of the First National Conference on Trichinosis, held in Chicago on December 12, 1952. Mr. Van Derwerker, chief of the municipal and rural branch of the Division of Sanitation, is Public Health Service representative on the Continuing Committee of the National Conference on Trichinosis.

Wright and his associates, on the basis of the studies at the National Institutes of Health, estimated that 4.5 percent of the number infected had sufficiently heavy infections to have developed clinical symptoms (6). If these figures could be assumed to be applicable to the present population, it would mean that millions of Americans alive today have been infected to some extent with the parasite, and it seems probable that many of these persons have had clinical symptoms. Further, on the basis of the aforementioned studies the number of cases expected annually would be several thousands.

Although trichinosis is a reportable disease in 44 States, the disease is seldom diagnosed clinically, and infections other than those in epidemic form are usually unrecognized. The fact that for the 10-year period, 1942 through 1951, an average of only 336 cases was reported annually to the Public Health Service illustrates this point. According to unpublished records, at least 1 epidemic occurred during this period which involved over 300 cases of trichinosis, and in this instance the disease was not diagnosed until some 24 days after the first symptoms were reported.

The practice of feeding raw or untreated garbage is known to be of primary importance in the spread of trichinae among swine. Schwartz (7) reports an incidence of trichinae in raw-garbage-fed hogs about five times as great as that in so-called grain-fed hogs. The consumption of raw, untreated, or inadequately cooked pork from garbage-fed hogs, furthermore, is considered primarily responsible for the high incidence of *Trichinella spiralis* in man (8,9). In both England and Canada, the sterilization of all garbage fed to swine has been

required by law for many years, and in both of these countries the incidence of trichinosis is relatively low.

Vesicular Exanthema Epidemic

The recent nationwide epidemic of vesicular exanthema, a virus disease in swine, has focused new attention in this country on the dangers of feeding raw garbage to swine. As a result of this epidemic, there are indications of strong support among the swine industry and the agricultural agencies for the elimination of feeding raw garbage.

On June 16, 1952, vesicular exanthema was detected among swine at a hog-cholera serum plant in Nebraska, and within 8 months infected swine had been found in 36 States scattered throughout the Nation. Epizootiological investigations by the U. S. Department of Agriculture and the various State agencies concerned indicated the possibility that garbage containing infected pork scraps had been fed raw to swine at a farm in Wyoming, and that contaminated swine from this State and from Nebraska had been shipped to other areas of the country before the disease was recognized. Most of the outbreaks in the other States were also identified with establishments where garbage was fed raw to swine, and the probable vehicle of infection was found to be contaminated pork scraps in the garbage.

Vesicular exanthema, though not transmissible to man and therefore not of direct public health significance, has serious economic and agricultural implications. The U. S. Department of Agriculture reported on February 7, 1953, that since the beginning of the epidemic 100,801 animals in 32 of the States involved had been disposed of by burial or special processing, and that 44,821 animals are awaiting disposal. It is evident, therefore, that the losses to swine raisers and allied industries and the costs to State and Federal governments for indemnities will be many millions of dollars. And to these must be added the costs of disinfecting plants, stockyards, and railway stock cars, of supervising disinfection, and other similar expenses, as well as losses resulting from restraint of livestock movement as a result of quarantines.

An additional concern to agricultural authorities is the fact that the symptoms of vesicular exanthema in swine are almost identical to those of foot-and-mouth disease. The control of foot-and-mouth disease depends so much on prompt diagnosis, slaughter of the infected herd with burial on the premises, and thorough disinfection of the entire area and plant that any delay in diagnosis of vesicular disease could well be disastrous to the livestock industry of the Nation.

Public Health Considerations

Thus, since disinfection of garbage fed to swine is of major importance in the eradication of both trichinosis and vesicular exanthema, combining the public health concern over trichinosis with the agricultural and economic concern over vesicular exanthema is a logical and necessary step. In addition to the public health worker's concern with trichinosis control, he is concerned with sanitary disposal of community solid wastes. For example, in some areas where the practice of feeding garbage to swine was discontinued during the epidemic, the garbage was disposed of by dumping it into a convenient river, thus creating a water pollution problem. Also, of course, he is concerned with such problems of hog farm sanitation as insect and rodent control and nuisance abatement.

Probably the best disease control measure, as well as sanitation measure, would be the discontinuance of raising swine on garbage and the disposal of garbage in incinerators or sanitary landfills or the utilization of it as dried feed or fertilizer compost. However, it is estimated that about 1,500,000 hogs are raised annually in the United States either wholly or partly on commercial garbage. Although they represent less than 2 percent of the hog population in this country, the shift away from garbage feeding would have an obvious economic impact. Until such a step is taken, therefore, the next best solution appears to be disinfection of garbage before it is fed to swine.

The Public Health Service's part in the regulation of garbage-feeding practices concerns primarily the interstate shipment of garbage. In 1941, an Interstate Quarantine Regulation

(section 72.23, 1947 revision) was issued, requiring that any garbage shipped or transported across State lines must be heated to 212° F. for 30 minutes before being fed to swine. Prior to the 1952 outbreak of vesicular exanthema, seven of the States and the Territory of Hawaii had similar regulations. Since the outbreak 9 States and Alaska have adopted regulations and/or legislation requiring heat-treatment of garbage used for swine feed, and at least 28 other States have either introduced similar measures in their legislatures or are preparing to do so.

USDA-PHS Control Measures

Recognizing the importance of the public health worker's role in the sanitary disposal of garbage, the U. S. Department of Agriculture last year requested the assistance of the Public Health Service in its vesicular exanthema eradication program. The Department urged the Federal Security Administrator to take emergency measures to insure enforcement of the Interstate Quarantine Regulation concerning garbage and expressed the hope that the Public Health Service would take appropriate steps to stimulate and assist State programs requiring disinfection of garbage fed to swine.

In accordance with the pursuant understanding, the U. S. Department of Agriculture has been concerned primarily with measures designed to arrest the current outbreak of vesicular exanthema. These include supervision of disinfection of contaminated yards, pens, and railway stock cars; quarantine of affected areas; and a program for disposal of and indemnity for condemned swine, and the cleaning and disinfection of infected premises.

Both the Department and the Service have, of course, been interested in the development of State programs for controlling the feeding of raw garbage to swine. In view of the lack of published information on methodology of disinfecting garbage, they worked together in compiling and publishing a summary of all available material on the subject (10). This activity pointed out the need for further research concerning heat-treatment systems,

equipment, economics, and related time-thermal characteristics required for disinfection. Iowa State College has recently applied for a Public Health Service grant to study time-temperature requirements for effective disinfection of garbage in relation to various methods of heat treatment.

The Public Health Service has also been co-operating in the vesicular exanthema eradication program through more effective control over the interstate shipment of raw garbage. In August 1952, the Federal Security Agency regional offices were requested to determine the extent of current violations of the Interstate Quarantine Regulation concerning garbage. These regional surveys have resulted in considerable program progress in certain major metropolitan areas and in a number of border areas where interstate shipment of raw garbage has been practiced.

Intrastate Regulation

Intrastate as well as interstate regulation of garbage-feeding practices is essential if the spread of garbage-borne diseases is to be controlled. In many States, disinfection of garbage is still not required, and many of the existing programs need strengthening.

A logical first step in developing intrastate control programs is a survey of garbage collection and disposal practices in each State. A basic data form (PHS Form 1764) has been developed by the Public Health Service for use in such surveys and has been made available to the States. Use of this form will permit collection of comparable data and, with the cooperation of State and local health departments, it should be possible to develop a nationwide inventory of practices. Such data should facilitate practicable planning of control efforts locally as well as in the States and for the Nation as a whole.

A second important step is the enactment of State legislation requiring the disinfection of all garbage used for swine feed and proper sanitation of hog farms. A suggested guide for such legislation, based on present regulations and experience in various States, has been prepared by the U. S. Department of Agriculture.

ture and the Public Health Service. This guide is available through the Federal Security Agency regional offices. It provides technical data which will aid the States in developing legislation that is not only legally sound but also practical. For example, it is usually more practical to require treatment of garbage at the feeding farm than at its source; also, the requirement of a license or a permit has been found to be the most practical method of administering a program.

Although disinfection of garbage is the prime factor in the control of trichinosis and vesicular exanthema, the complete sanitation of the establishment involved should be given serious and continued consideration in any State control program. Sanitary solid waste disposal includes not only the disinfection of the potential vector of disease, but also the handling of the media so as to minimize insect and rodent breeding and to prevent water pollution. Nuisance abatement is also a factor and should be taken into account.

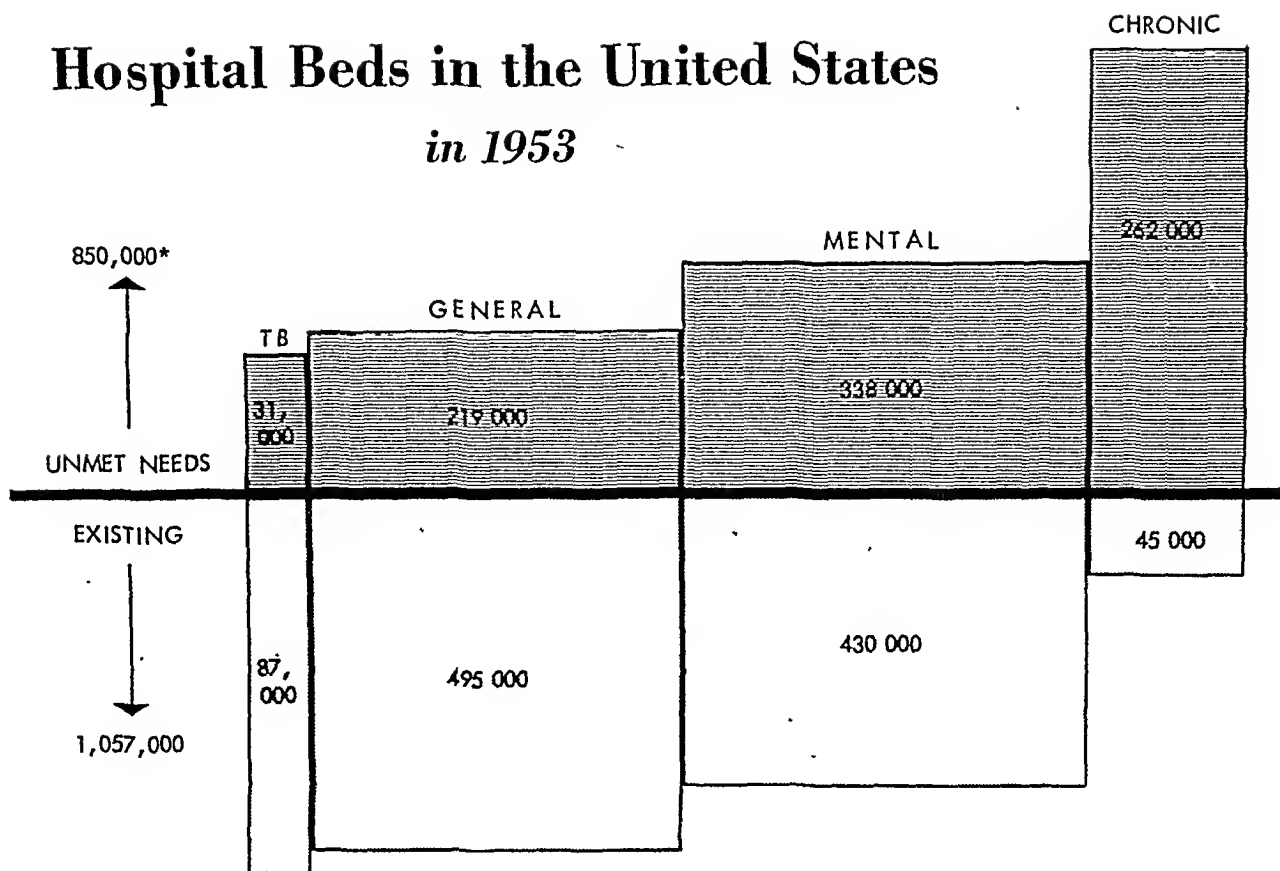

For many years, community solid waste problems have been more or less neglected by health workers, but the fact that these problems have serious health implications is now receiving increasing recognition. The recent vesicular exanthema outbreak has underscored the epidemic possibilities of one improper method of garbage disposal and has provided support for trichinosis control efforts. The time is appropriate for a vigorous nationwide program for proper treatment or disposal of garbage to control disease and to improve sanitation.

Hospital Beds in the United States in 1953

*Exclusive of 117,000 Federal hospital beds. All data in this chart as of January 1, 1953.

By JOHN W. CRONIN, M.D., MAURICE E. ODOROFF, M.A.,
and LESLIE MORGAN ABBE, B.S.

HOSPITAL BEDS are symbols of hospital services and are not an end in themselves. They do provide a useful measure of the physical facilities at hand for furnishing hospital services. The capacity to provide adequate health care in a community or a nation can be gauged substantially by the number of beds available, in relation to the number of people living in the area.

Prior to 1946 the building of new hospitals and hospital additions in the United States was

Dr. Cronin is chief of the Division of Hospital Facilities, Public Health Service. Mr. Odoroff is chief and Mr. Abbe is assistant chief of the program evaluation and reports branch of the division.

sporadic, proceeding slowly in some communities and rapidly in others, according to local pressures and means and without regard to any general pattern or orderly plan. At the same time many communities and sections of the Nation had little or no available hospital care within ready reach. The end of World War II made possible a renewed interest in providing for many domestic needs. Physical facilities for the Nation's health became one aspect of this interest.

A broad program was launched in 1946 by Federal legislation to assist the States to inventory their existing hospitals, to define the total need for hospitals, and to map out a construction program to provide needed hospital and health center services. Financial assist-

ance was included, both for planning and construction. This legislation, the Hospital Survey and Construction Act (Public Law 725, 79th Cong.) has been popularly known as the Hill-Burton Act. Its administration was placed under the Surgeon General of the Public Health Service, as a part of the basic Public Health Service Act.

It required more than a year to develop initial inventories and comprehensive plans. Hospital inventories existed, compiled by the American Hospital Association and the American Medical Association, but the idea of inventory-plus-statewide-program was entirely new. The first complete set of these comprehensive plans reflected the facts as of about January 1, 1948. Today, after 5 years of experience on the part of the State hospital agencies, the record has been refined and general planning is based upon more intimate knowledge of local situations.

This report appraises the situation nationally and locally, as reflected by the current State hospital plans under the Hospital Survey and Construction Act. It also comments on the influence of the Hill-Burton program during 5 years of operation and refers to current problems relating to standards of need and standards for the degree of Federal aid now appropriate.

Where We Are Now

In the Nation as a whole we now have 1,218,000 existing hospital beds, according to State plan inventories as of January 1, 1953. These plans excluded Federal beds. This total is 202,000 more than was recorded in the first Hill-Burton inventory as of January 1, 1948. Of these, however, 161,000 beds are classified by the State agencies as nonacceptable on the basis of fire and health hazards, so that our net acceptable plant for all purposes is 1,057,000 beds. Almost one-half of this total, or 495,000 beds, is in general hospitals; mental hospitals have 431,000 beds; tuberculosis hospitals, 86,000 beds; and hospitals for chronic care, 44,000 beds.

The Hospital Survey and Construction Act establishes standards of need, for planning purposes, in each category of hospital. These standards are limits for construction with Fed-

eral assistance and do not preclude State planning to higher levels if warranted. For most States, however, the standards established in the Hill-Burton Act are much beyond the level of existing facilities. By these standards about 850,000 additional beds are needed nationally to provide adequate hospital care for all the people. Of these, 336,000 are needed in mental hospitals, 262,000 in chronic hospitals, 219,000 in general hospitals, and 31,000 in tuberculosis hospitals. Percentagewise, the Nation has 77 percent of its need met in tuberculosis facilities, 69 percent in general hospitals, 56 percent in mental hospitals, and 14 percent in chronic hospitals.

The historical record, by years from 1948 to 1953, for each category appears in table 1. By definition under the present regulations, this inventory excludes beds for civilians in Federal hospitals. These are chiefly in facilities of the Veterans Administration, plus a comparatively small number of beds in the hospitals operated by the Indian Service and the Public Health Service.

During the 5 years for which comprehensive State planning has been carried on, considerable net progress has been made in general hospitals: 107,000 additional acceptable beds are recorded, a gain of 28 percent. Tuberculosis beds have also increased more than 20 percent. Mental and chronic beds, on the other hand, while increasing slowly, are not keeping up with growth in population and obsolescence. In both these categories the remaining need is greater than in 1948. This constitutes one of the major challenges facing the Nation today in meeting the need for adequate hospital services.

National trends and national totals do not accurately reflect the real picture in regard to specific regions of the country. Among the States, wide differences exist as to relative status in providing an adequate hospital plant. Similar differences exist among the major socioeconomic regions of the Nation. Generally speaking, the States with large means have the least unmet need, while the least wealthy States have the greatest need. Thus, New York and Connecticut have only about 3.2 beds per 1,000 population still required, for all purposes. Mississippi and Alabama each need 8.3 more

beds per 1,000 population, while the national average of unmet need is 5.5 beds per 1,000 population. Regionally, the greatest unmet need for general hospitals is still in the southeastern States, although substantial progress has been made here during the past 5 years.

Similar contrasts appear for mental hospitals. The unmet need, nationally, is still 2.2

beds per 1,000 population. In New England it is only 1 bed per 1,000, but throughout the southeastern and southwestern States this need is nearly 3 beds per 1,000. Comparative positions are shown in the maps and in table 2.

The Hospital Survey and Construction Act requires that a coordinated system of general hospitals be planned within each State, under

Table 1. Civilian hospital beds in the United States and Territories, 1948-53

which regional hospital centers would provide leadership, specialized care, and consultation for smaller community hospitals within the region. Under the Hill-Burton program the United States is composed of 375 such regions, as defined in present State plans. Studies of these regions show that there are actually wide differences as to the level of facilities now available in single hospital regions. In Arkansas the proportion of acceptable facilities available varies from region to region, from about 25 percent of need met to nearly 75 percent. In Florida, it ranges from 42 percent to 87 percent; in Kansas, from 52 percent to 92 percent; and in Idaho, from 45 percent to 96 percent. Obviously, State totals may obscure important

differences among hospital regions in the present available plant.

For local communities there are also areas of acute need with little or no available hospital plant. A recent check shows 250 hospital areas still without any acceptable hospital facilities. These areas include about 3 percent of the Nation's population and require some 13,000 beds to meet standards for general hospital care. This study also shows that about 5 percent of the population of the Nation live in areas where less than 25 percent of the general hospital facilities needed are available. These facts give some indication of the work yet to be done.

Effect of the Hill-Burton Program

The act requires a continuous inventory and positive planning of hospital expansion in each State. This has greatly stimulated orderly growth of the Nation's facilities for protecting the health of its people. Its direct encouragement of construction has been substantial, when measured by the dollar volume of hospital construction (1,2). During the last 3 years the value of work placed on Hill-Burton projects has averaged about one-third of all non-Federal hospital construction (see chart).

A number of additional benefits also have accrued (3). Perhaps the most significant, in regard to improving the quality of service,

have been the very rapid increase in State statutes establishing hospital licensing, improved architectural design, attracting of physicians to rural communities, and creating a greater awareness of the problems of adequate care for chronic illness.

The effect of the hospital survey and construction program is quite significant in regard to the distribution of projects assisted. This is governed by the statutory formula for allocation among the States of the annual appropriation and by the conditions required as to a graduated scale for matching local funds. In each State, the formula for matching is based on population, weighted by its financial ability. As a result, the greatest Federal assistance has

been given in the least wealthy States. The record shows that remaining need is still the greatest in these States.

Expressed broadly, the Hill-Burton program in 5 years has assisted in building about 1.0 bed per 1,000 population in the neediest States. These are States where the remaining additional need is still about 8 beds per 1,000 population. A proportionally lesser volume of assistance—about 0.3 beds per 1,000 population—has been accorded States with the least unmet need. In these States the remaining need is now under 3.5 beds per 1,000 population. Comparative study of the relation between remaining need and the degree to which these States are rural in character shows that the greatest need occurs in those States which have the highest proportion of population living in rural areas. In brief, Hill-Burton aid has been distributed to the greatest degree in those States which are least wealthy, most rural, and with greatest proportional unmet need.

Within the several States, distribution of assistance to specific projects has been governed by a priority system based on unmet need, as established in the State plan. In consequence the stimulus of Federal assistance has encouraged many communities where unmet need was the greatest to raise local funds for matching Federal grants, in accordance with the intent of the act. Recent studies have indicated that 38 percent of all general hospital beds added with Hospital Survey and Construction Act assistance have been in places under 10,000 in population; 31 percent in places of from 10,000 to 50,000 population; and 31 percent in metropolitan cities of over 50,000 population. Nearly 600 new projects have been placed in communities which previously had no acceptable hospital. At the other end of the scale, 21 teaching facilities at university medical centers have been assisted in 18 States.

Major emphasis has been placed by State agencies on Hill-Burton assistance to general hospital projects. As of January 1, 1953, general hospital beds added by approved projects amount to 73,168, of a total of 96,428 beds in all types of hospitals. A gradual change in this emphasis for most States appears important, if a reasonable balance between categories of facilities is to be attained.

Value of construction put in place

The hospital survey and construction program makes funds available not only for hospitals but for public health centers. In the Nation to date 377 such projects have been approved. The largest number of these, 283, will serve the 30,000,000 people in the 11 southeastern States. In this region these projects constitute a substantial increase in facilities available for preventive medicine and extend a means of providing for good health at a very moderate outlay. These projects represent a total expenditure of \$28,000,000, or about 2 percent of the estimated total cost of \$1,588,000,000 for all projects assisted through January 1, 1953, by Hospital Survey and Construction Act funds.

Problems Ahead

After 5 years of active operation of this co-operative Federal-State program, problems are emerging which were not at first anticipated. One group of problems involves the technical aspects of setting more precise standards of need:

1. The standard for tuberculosis beds required, as gradually evolved since 1917, is not on a population basis, but is related to the mortality rate. The mortality rate for tuberculosis continued to decline rapidly and dropped to a rate of 20 per 100,000 population for 1951. This is in contrast to a rate of 46 in 1940 and 200 at

the turn of the century. New cases of active tuberculosis, however, continue to be discovered at a rate which is declining very slightly. It now seems clear that new standards based on incidence of active cases should be substituted for the present basis of planning under the act.

2. One of the important innovations in the Hill-Burton inventory is the distinction made between acceptable and nonacceptable beds. For planning purposes, only acceptable beds are recognized as counting against total need. There is still a considerable variation among State plans as to the degree to which nonacceptable beds have been identified and taken into account for planning. As shown by table 1, nonacceptable beds today amount to about 15 percent of all existing beds in the Nation. In some States only a few such beds have been distinguished. Sometimes this arises from the assumption that facilities licensed must be held acceptable, even though there may be substantial public hazards existing. For example, Kentucky and Alabama have recorded only about 0.25 beds per 1,000 population as unacceptable, while Mississippi, Louisiana, and Virginia report 1.5 beds or more per 1,000 population as unacceptable. Three States, Georgia, Kansas, and Connecticut, have recently modified their records by increasing the designation of unacceptable beds very substantially. There is a need for the establishment of practical and comparable minimum standards of acceptability.

3. A third technical problem relates to the role of existing beds for civilians in Federal hospitals. Supporters of the viewpoint that these beds should be included in State hospital plan inventories are increasing. According to last available reports there are existing about 46,000 such general hospital beds for civilians, 55,000 mental hospital beds, and 15,000 tuberculosis hospital beds, which are not now recorded in Hill-Burton plans. These are not distributed uniformly among the States in relation to the population, and cannot all be regarded as reasonably accessible. They still constitute a considerable proportion of the total actual hospital plant. For the present they could probably be added to the record without changing the levels of total need, since many States find

these goals greater than the apparent ability of their people to achieve at this time.

A second group of problems relates to broad policy for standards governing the degree of Federal assistance:

1. The Hospital Survey and Construction Act constitutes a fairly advanced form of grant-in-aid principles. It has the practical effect of producing its maximum program in States of minimum income and greatest need. Various proposals have arisen for modifying this distribution of aid among the States and also for requiring State support in addition to local support.

2. Within most States, there are marked differences among hospital areas in need and financial resources. The present Hospital Survey and Construction Act recognizes this situation. An option is provided which varies the percentage of Federal assistance on specific projects, as an alternate to selecting a single percentage for all projects in any one State. Interest in using this option is increasing, as it facilitates actual construction in remaining areas having acute need and restricted means.

Summary

1. The number of existing hospital beds provides a useful measure of the hospital services available to a community and to the Nation.

2. Continuing inventories and comprehensive State plans under the Hospital Survey and Construction Act of 1946 define total need for hospital beds and indicate a positive construction program.

3. According to these State plans (which do not include Federal beds) the United States on January 1, 1953, had 1,057,000 acceptable hospital beds for civilians, or 56 percent of the total need. The existing national plant for each category of hospital amounted to the following percentages of total need: tuberculosis 77 percent, general 69 percent, mental 56 percent, chronic 14 percent.

4. Marked differences exist among the States, and among the broad socioeconomic regions of the country, in the relative number of hospital beds available per capita. Present resources, or their lack, are closely related to the economic ability of the area.

5. The Hill-Burton program has had a considerable impact, through 5 years of active operation, in beginning to reduce differences in unmet need for beds—locally, by States, and by broad socioeconomic regions. The total dollar value of work put in place with Hill-Burton aid has averaged about one-third of all non-Federal hospital construction. Its distribution has been both rural and urban. Although the actual number of beds for mental and chronic care has increased considerably since 1948, growth in population and the need for replacing obsolete facilities has increased the net deficit of beds needed in these categories. On the other hand, in this period the unmet need for general hospital beds was reduced by one-fourth, and for tuberculosis beds by one-half.

6. Although statewide planning for hospital construction is now accepted practice, through

the encouragement of the Hill-Burton Act, there are still technical problems of defining more precisely the standards of need. Problems also remain, as to the appropriate amount and distribution of financial assistance to local communities, in order to level out deficits in hospital beds and attain facilities for the promotion of adequate health care throughout the Nation.

Training Courses in Diabetes Control

The Division of Chronic Disease and Tuberculosis, Public Health Service, announces a series of six courses for training in diabetes control to be held at the Diabetes Study and Training Center, Boston, Mass. Designed for public health administrators, physicians, nurses, health educators, dietitians, nutritionists, medical technologists, and medical social workers, the week-long courses will consist of discussions, demonstrations, and field trips, with opportunities for individual consultation. At present only two of the courses have been scheduled. Announcements of the dates of the others will be made periodically.

The courses are as follows:

A diabetes program in public health (September 21-25, 1953). Designed for all categories of public health workers involved in the planning and operation of diabetes public health programs.

Group teaching of patients (May 25-29, October 5-12, November 30-December 4, 1953). Planned primarily for personnel concerned with organizing and conducting group classes for patients with diabetes and their families.

Nursing aspect of a public health diabetes program (dates to be announced). Planned for nursing personnel in health departments, voluntary agencies, hospitals, clinics and industry.

Nutritional aspects of a public health diabetes program (dates to be announced). Planned for dietitians and nutritionists in public and private health agencies and hospitals.

Laboratory aspects of a public health diabetes program (dates to be announced). Intended for medical technologists in health agencies and hospitals who are concerned

with methods of determination and the merits of various blood sugar tests; operation of a mass detection program; and problems associated with the collecting, shipping and storage of blood.

Organization and management of a diabetes clinic (dates to be announced). Planned for personnel concerned with the functioning of a diabetes clinic. The course will be sponsored and given in cooperation with the clinical staff of a large city hospital.

Enrollment in the courses will be limited to 10 persons per course. No registration or tuition fee is required. Further information and application forms may be obtained from the Diabetes Study and Training Center, Public Health Service, 639 Huntington Avenue, Boston 15, Mass. Applications must be received 1 month in advance of date of course.

the turn of the century. New cases of active tuberculosis, however, continue to be discovered at a rate which is declining very slightly. It now seems clear that new standards based on incidence of active cases should be substituted for the present basis of planning under the act.

2. One of the important innovations in the Hill-Burton inventory is the distinction made between acceptable and nonacceptable beds. For planning purposes, only acceptable beds are recognized as counting against total need. 1. The number of existing hospital beds provides a useful measure of the hospital services available to a community and to the Nation.

2. Continuing inventories and comprehensive State plans under the Hospital Survey and Construction Act of 1946 define total need for hospital beds and indicate a positive construction program.

3. According to these State plans (which do not include Federal beds) the United States on January 1, 1953, had 1,057,000 acceptable hospital beds for civilians, or 56 percent of the total need. The existing national plant for each category of hospital amounted to the following percentages of total need: tuberculosis 77 percent, general 69 percent, mental 56 percent, chronic 14 percent.

4. Marked differences exist among the States, and among the broad socioeconomic regions of the country, in the relative number of hospital beds available per capita. Present resources, or their lack, are closely related to the economic ability of the area.

matters. Local health officers in slightly more than half the States have authority to issue orders; local legislative bodies in most States may pass ordinances; and in slightly less than half the States the legislative body may also issue rules; in 30 States local legislative bodies may prescribe regulations. The State legislature rarely has the power to issue rules, regulations, and orders pertaining to public health. Likewise, local health departments very seldom have such authority. One State has a regulation which permits the State board of health to

issue rules and orders. One other State permits local health officers to issue orders by practice without any statutory provision.

State and local boards of health and State and local health officers most frequently are charged by law with the enforcement of State laws, regulations, and orders pertaining to public health (table 2). There are a few States in which the enforcement powers of the State board of health and the State health officer extend to local laws, regulations, orders, and ordinances. From half to three-fourths of the

¹ Refers to States having statutes applicable only to some types of governmental areas or to specific matters.

States permit local health officers or local boards of health to enforce local laws, regulations, orders or ordinances. Local legislative bodies infrequently have powers of enforcement. In many States the matters pertaining to public health are primarily enforced by local police officials and by public prosecutors with the health authorities' only responsibility being that of making the charge or complaint.

Delegation of Public Health Powers

The majority of States delegate their powers with respect to public health to local areas—at least in some matters (table 3). As many as 32 States delegate powers by statute to local health officers and 27 States make such delegations to local boards of health. Additional States delegate powers by practice without statutory authority. In at least some of the States the delegation of power is limited in that the State board of health or health officer retains supervisory authority. One State law prohibits this delegation of power.

All but two States give the State health authority the power to act in the absence of a local health department, or upon failure of the local health department to take action. In one of the two States without such power, the State assumes this responsibility by practice. In six States, however, this power is restricted to certain areas of responsibility, such as epidemic disease prevention or control.

Specific Powers of Local Authorities

In only a few States do local health officers and boards of health have power of subpena, or

power to administer oaths, to issue injunctions, to conduct hearings, or to issue licenses. Most generally, authorization for such action is provided by statutes as indicated in table 4. Local boards of health are given such powers about twice as often as local health officers. Frequently these powers are applicable only to certain local governmental areas and occasionally are applicable only with respect to certain public health matters. There are no regulations pertaining to these specific powers.

Table 5 lists several additional specific powers and indicates the number of States in which the State board of health, local boards of health, local health officers, and local legislative bodies are vested with these powers. The power of isolation and quarantine predominantly rests with State and local boards of health and local health officers. Nearly all States have statutory provisions for isolation and quarantine of communicable disease cases, but in some States such statutes are limited in their application to certain areas or may be invoked only under certain conditions. Local legislative bodies in slightly more than one-quarter of the States possess powers of isolation and quarantine for communicable diseases.

In almost all States the State board of health and local health officers have statutory power to make investigations and inspections, and, in at least three-fourths of the States, local boards of health also have such powers. Local legislative bodies in only six States have the statutory power of investigation and inspection with respect to public health matters.

Slightly less than three-fourths of the States have provisions of law permitting State and local boards of health and local health officers to abate public health nuisances. Nearly half the States have statutes granting this power to local legislative bodies, although these statutes are frequently limited to certain types of local areas or to certain types of nuisances.

Nearly three-fourths of the States have statutes which permit the State board of health to forbid gatherings in the interest of public health. More than half the States have laws granting local health officers this power, and nearly half the States grant such power to local boards of health. Local legislative bodies infrequently possess the authority to forbid public gatherings in the interest of public health.

All but two State boards of health have the power to collect vital statistics and disease reports either by statute or by statute and regulation. In Massachusetts the power to collect vital statistics reposes in the office of the secretary of State, and in New York the State health

officer has the power to collect vital statistics and disease reports. In addition, local health officers have power to collect vital statistics in 24 States and disease reports in 34 States. Local boards of health have power by statute to collect vital statistics in 12 States and statutory power to collect disease reports in 23 States with regulations supplementing statutory power in 1 State. These two powers are almost never given to local legislative bodies.

The power to initiate court actions and defend health departments against court actions is given to local health officers in 15 States, to the State board of health in 26 States, to local boards of health in 18, and to local legislative bodies in 6. In addition, this power is exercised by practice by the State board of health in 1 State, local boards of health in 1 State, local legislative bodies in 2, and local health officers in 1.

Judicial review of actions of local boards of health or local health officers is authorized by law in 25 States. It is done by practice in 11 others, and is authorized by practice only for cities in 1 State. Judicial review of the action of health officials is specifically prohibited by law under certain circumstances in 2 States and not commonly done in 9 other States wherein the law is silent on the matter. One State failed to supply information on this item.

² In one additional State this power is exercised by practice without statutory provision.

Summary

Data from the survey of State laws, regulations, and practices pertaining to the duties and powers of State and local boards of health, health officers, and health departments indicate that the power to pass public health laws and to issue regulations, rules, and orders generally rests with State and local boards of health and less frequently with State health officers, State or local legislative bodies, or local health officers. Authority to enforce State public health laws and regulations is generally assigned to State and local health officers; the enforcement of local laws and regulations is primarily the legal responsibility of local boards of health and health officers.

States generally delegate their public health powers to local boards of health, health officers, and local health departments. Almost all State health authorities have the power to act in the absence of local health departments, or upon the failure of local authority to take action.

Less than three-fourths of the States provide for judicial review of decisions made by boards of health or health officers.

Local health officers and local boards of health infrequently possess the power of subpoena, power to administer oaths, to issue injunctions, to conduct hearings, or to issue licenses.

Many State boards of health, as well as local boards of health and health officers, have the power to require isolation and quarantine of communicable diseases; to make investigations and inspections; to abate nuisances; to forbid gatherings in the interest of public health; to collect vital statistics; or to require disease reports. On the other hand, fewer of them have the power to institute court action or to defend their actions in the courts.

Achievements in World Health

In carrying out its constitutional role as "coordinating and directing authority in international health," the World Health Organization has made notable contributions toward the development of better health everywhere. Outstanding achievements during 1952 were summarized in an information kit, "Health Is Wealth," prepared by the Public Health Service in observance of World Health Day, 1953, as follows:

It gave direct technical aid to more than 100 governments and territories.

It made effective, on October 1, 1952, the new International Sanitary Regulations, designed to facilitate international travel and trade.

It took over, with the United Nations International Children's Emergency Fund,

responsibility for continuing the BCG anti-tuberculosis vaccination programs after the official end of the 1951 international campaign.

It maintained an international epidemic-warning service, continued to coordinate worldwide influenza research activities, and operated a tuberculosis research office and several brucellosis centers.

It provided emergency aid for several governments faced with epidemics and refugee health problems.

It recruited, for the United Nations Reconstruction Agency, a team of experts which visited Korea to work out a long-term plan for improving health and medical care, in addition to the technicians working on civilian health programs in South Korea.

An Experiment With Group Conferences For Weight Reduction

By A. L. CHAPMAN, M.D.

Ten overweight women in Alexandria, Va., who participated in group conferences on weight control, lost an average of 17.8 pounds each over a 20-week period. The entire class lost an average of 42.7 percent in excess weight, ranging from 13.5 to 131.5 percent. Weekly conferences were held between March 29 and August 25, 1952, at the Alexandria City Health Department.

Free discussion, centering first on nutritional and psychological orientation and later on self-analysis, was the guiding principle of the conferences. Losing a pound a week until the ideal weight was approximated was selected as each participant's arbitrary goal.

It was repeatedly emphasized that medical supervision of the group members was the sole responsibility of their own physicians. The group leader conducted the conference in such a way that the women would be motivated to decrease their caloric intake. Loyalty in attendance was stressed more than weight loss because it was believed that continued attendance eventually would bring about sufficient motivation to achieve weight reduction. At no time did a spirit of compulsion to lose weight prevail.

Amounts Lost

Four of the 10 women lost weight from the beginning and continued to lose at a rate of more than a pound a week. They were so well motivated that they lost 25, 27, 27, and 25 pounds, respectively, or 131.5, 93.1, 38.8, and 104.1 percent of excess weight. They never

seemed unduly upset by the need to restrict their diets.

The other six members found weight reduction more difficult. They needed special attention from the rest of the group, from the consultants, and from the leader. They seemed to resist decisions that might entail dietary restrictions and manufactured excuses when they failed to lose weight as fast as they had hoped. Eventually, one by one they submitted to the interest of the group and belatedly began to acknowledge the inevitability of eating less food if they truly wanted to lose weight.

Four members, told by their own physicians that they had low basal metabolic rates, lost 7, 13, 14, and 25 pounds, respectively, or 36.8, 43.3, 13.5, and 93.1 percent of their excess weight. The woman losing 93.1 percent of her excess weight reported that her dietary intake had to be cut to a low level to achieve this substantial reduction. One woman with heart disease lost 12 pounds. Her percentage of excess weight loss was 24.0.

Methods

Decreased caloric intake was stressed during the first four sessions until a significant degree of weight reduction was achieved. From then on every effort was made to help members include the protective food substances and an adequate amount of protein in their diets.

A weight chart was prepared for each member. A line was drawn on the chart, starting at the current weight of the individual and declining at a rate of one pound a week for 20 weeks. Weights were taken before every meeting and recorded on the charts. In this way, each woman had a graphic record of whether she was losing her weekly pound or going in debt to the group. The charts revealed the members who were having the most difficulty controlling their appetites and who needed encouragement from the more successful members.

Early in the series, each one was asked to name the food item in her diet which she believed to be the worst offender from the standpoint of obesity. Bread, cake, pie, candy, ice cream, soft drinks, and sugar and cream in coffee were mentioned. Each woman pointed to one or two of these foods as significant in

Dr. Chapman, Public Health Service medical director for Region III, formerly was chief of the Division of Chronic Disease in the Bureau of State Services, Public Health Service.

From Michigan comes an informal account of another effort at weight control using the group method. This was self-generated by group members, sparked by a housewife who was stimulated by reading an article in a popular magazine of national circulation. The housewife writes:

"We now have a thriving class of 18 women who have shed 91 pounds as of our fourth meeting. Just as in the reports of other groups, we have our well-motivated, steady losers, some who are running into real difficulty restricting themselves, and one who has steadily gained since joining our class. She is our unmarried member, a teenager 40 pounds too heavy, working in her father's candy store!

"We have enlisted the help of the State department of health, which has offered materials, personnel, and even a meeting place should we need it. Also, the director of the State department of mental health is going to pay us a visit. We plan some tape-recording exchanges to further our understanding of the problem. Pamphlets and films have been used as background material and as diet guides.

"Sources of therapeutic help are limited here. We have no county health doctor, and we hesitate to ask one of our terribly busy private physicians to assume advisership, so each member has depended on her own doctor for advice. I have a short interview with some doctor each week about some of the problems that come up."

causing her own overweight condition. Great stress was placed on discussing the nonfattening substitutes for high caloric foods.

Each woman was then asked to forego indefinitely the one food which she believed to be the chief cause of her own obesity. As a result, the class got off to an encouraging start, which did much to convince the group that overweight is caused by overeating, and that it is controllable. Every member except one with hypothyroidism lost weight by the end of the first week. She lost 3 pounds during the first 2 weeks.

For several weeks, members were encouraged to keep diet records to help them understand the magnitude of their caloric intake. Many women fail to realize the amount of calories accumulated by their habit of eating frequently throughout the day. It soon became obvious that several women were consciously or unconsciously omitting food items from their diet records. As the weeks passed and group confidence increased, the daily records became more accurate.

Education

Educational efforts were limited to imparting simple and basic nutritional concepts. The Metropolitan Life Insurance Co. booklet "Overweight and Underweight" was read aloud by the class. As each paragraph was read, its contents were discussed. Questions brought up were usually answered by members of the group. Three films, "Losing to Win," "Proof of the Pudding," and "Weight Reduction through Diet" were shown at opportune intervals.

Upon the expressed wishes of the members, special consultants were invited to participate in the discussions. On two occasions, a public health physician, trained in nutrition, discussed basic food elements and protective food substances. On another, a psychiatrist attended and developed a discussion on self-analysis, which was continued at two following conferences when a psychiatric social worker was present. Late in the course, a nutritionist explained how to plan menus in terms of food portions rather than in terms of grams. She also discussed individual dietary problems.

When the subject of self-analysis was introduced, several papers on the emotional components of obesity and personality traits of obese people were read and discussed freely. The group showed little or no resentment to the viewpoints expressed in the papers but instead seemed willing, often anxious, to translate the verities contained in them to other members of the group in terms of their own experiences.

Mortality in the United States, 1900–1950

BY TAVIA GORDON

DURING THE LATE eighteenth and nineteenth centuries, death rates for the western world were slowly moving downward. Great pestilential epidemics swept across Europe and North America during this period, but by the beginning of the twentieth century it was evident that the application of discoveries by the pioneer bacteriologists and epidemiologists had brought about a substantial control of these recurrent scourges, and pointed the way to a further reduction in mortality.

Only the most optimistic, however, could have foreseen the reduction that actually occurred during the next 50 years. In 1900, the first year for which the Bureau of the Census received death records from the States, the death rate for the District of Columbia and the 10 States submitting records was 17.2 per 1,000 population. By 1950, the rate was at a record low of 9.6 per 1,000 for the entire United States, a reduction of 44 percent. The increase in medical knowledge, the more general availability of medical care, improvements in environmental sanitation, and the vigorous prosecution of public health programs all contributed to this phenomenal improvement. In addition, the rise in the standard of living and changes in the character of certain diseases played important roles in this decline.

Infectious Diseases

These factors proved most effective in the control of some infectious diseases. The sharp decline in mortality for diarrhea and related

diseases, shown in figure 1 as "specified gastrointestinal diseases," probably was mainly due to improved sanitation. The death rate for these causes declined 96 percent between 1900 and 1950, from 154.7 deaths per 100,000 population to 6.2 per 100,000. At the same time, typhoid fever almost completely disappeared as a cause of death. Protection of water and milk supplies and better sewage disposal facilities in cities and many rural areas led to a decline in typhoid fever incidence. The death rate fell from 31.3 in 1900 to 0.1 per 100,000 in 1950.

Mortality for the communicable diseases of childhood fell sharply between 1900 and 1950. This has been attributed to such factors as changes in the character of some of these diseases, more regular medical care for infants and children, widespread immunization programs, and the steady improvement in diet and hygiene. By 1950 death rates for diphtheria, measles, whooping cough, and scarlet fever had declined to a small fraction of their values at the beginning of the century (figs. 2 and 3). In 1900, this group of diseases was responsible for 242.6 deaths per 100,000 children under 15. In 1950, these diseases together caused fewer than 5 deaths for every 100,000 children.

Infant and Maternal Mortality

From the early part of this century, the medical and public health professions made special efforts to reduce the risks surrounding birth and infancy, and the decline in deaths under 1 year of age was truly impressive. Between 1915, when the birth-registration area was established, and 1950, the infant mortality rate declined from 99.9 deaths under 1 year of age per 1,000 live births to 29.2.

Mr. Gordon is an analytical statistician with the mortality analysis branch, National Office of Vital Statistics of the Public Health Service.

The maternal mortality rate, which did not respond as readily to the efforts to safeguard childbirth, remained high until the 1930's. At that time it began a slow decline, which accelerated rapidly after 1936 as a result of the combined impact of the studies of medical committees on maternal mortality, the discovery of the antibiotics, and improved techniques to control hemorrhage.

Tuberculosis, Influenza and Pneumonia

By 1950, the major causes of death remaining among infectious diseases were tuberculosis and influenza and pneumonia. Mortality declined more slowly for these causes than for the other infectious diseases shown in figures 1, 2, and 3, but the rate of decline accelerated in the late 1940's.

The tuberculosis death rate decreased by as great a percentage between 1945 and 1950 as it had in the preceding 15 years. The death rate of 40 per 100,000 in 1945 was nearly halved by 1950, reaching the low of 22.5 per 100,000 popu-

Figure 1. Death rates for specified gastrointestinal diseases, tuberculosis (all forms) and influenza and pneumonia: death-registration States, 1900-1950.

NOTE: "Specified gastrointestinal diseases" includes dysentery, all forms; gastritis, duodenitis, enteritis, and colitis; and diarrhea of the newborn.

Figure 2. Death rates for diphtheria and typhoid fever: death-registration States, 1900-1950.

lation, and estimates for 1951 and 1952 indicate that this rapid decline is continuing. Part of the recent change may be the result of the cumulative effect of hospitalization and medical care programs. Since tuberculosis appears to have been responsive to improvements in the standard of living over many decades, the general prosperity of the last 10 years may have also contributed to the recent trend.

With the introduction of sulfonamide and antibiotic therapy, which provided the first effective medical treatment for certain types of pneumonia, the death rate for influenza and pneumonia fell rapidly (fig. 1). Between 1900 and 1937, the death rate for these causes fluctuated widely, but it never fell below 95.7 per 100,000. In 1918, the year of the great influenza pandemic, influenza and pneumonia caused 588 deaths per 100,000 population.

During the 5 years before the introduction of sulfa therapy, 1932-37, the median death rate for influenza and pneumonia was 104.2 per 100,000. The rate dropped in 1938 to 80.4. In subsequent years mortality for these causes continued to decline rapidly. In 1950, the death rate for influenza and pneumonia was

31.3 per 100,000. It remains to be seen, however, how permanent this reduction will be.

The new therapy responsible for these recent changes constitutes a major event in the history of medicine, even though its immediate effect on the total death rate has not been very great. Some of its most dramatic results have been demonstrated for certain diseases of great virulence, like Rocky Mountain spotted fever, psittacosis, plague, and typhus fever, and in a further reduction in death rates for the common infectious diseases. It contributes a powerful reinforcement in the treatment of infectious diseases and in reducing their severity.

Accidents and Chronic Diseases

Not all the changes in mortality since 1900 have been favorable. In 1900, motor vehicle accidents were not even distinguished as a cause of death in the cause lists then current. Since that time motor vehicles and motor vehicle fatalities have become increasingly common. In 1950, the death rate for motor vehicle accidents was 23.1 per 100,000—higher than the death rate for tuberculosis. The mortality for other

Figure 3. Death rates for whooping cough, measles, and scarlet fever: death-registration States, 1900–1950.

Figure 4. Death rates for the younger ages: death-registration States, 1900–1950.

accidents, however, declined during this period from 72.3 deaths per 100,000 in 1900 to 37.5 in 1950.

The chronic diseases as a whole did not show a decreasing mortality in this period, so that as the death rates fell for the infectious diseases the chronic diseases increased in relative importance. In 1900, the cardiovascular-renal diseases and malignant neoplasms accounted for only 24 percent of the recorded deaths. In 1950, 68 percent of all deaths were ascribed to these two groups of causes.

Mortality by Age

Each cause of death has a characteristic age distribution. Consequently, a reduction in mortality for specific causes affects the death rate for the various ages by differing amounts. The infectious diseases were the preponderating causes of death for the younger age groups in 1900. The radical reduction in mortality for these diseases, therefore, had its most marked effect on the death rates at the younger ages and progressively less effect for each older age group. For children aged 1 to 4 years, the death rate dropped from 19.8 per 1,000 in 1900 to 1.4 per 1,000 in 1950, a decrease of 93 percent; the decrease for the age group 35–44 in this period was 65 percent (fig. 4).

Mortality in the older age groups, for which the major causes of death are the chronic diseases, showed decreases of considerably less

magnitude. The death rate for the age group 45 to 54 years decreased 43 percent, from a rate of 17 per 1,000 in 1900 to 8.5 in 1950, and the indicated rate of decrease was smaller for each older age group. For the ages above 85, where the reporting of data is recognized to be unreliable, it is doubtful if any real change in the death rate occurred between 1900 and 1950.

Comparisons With Other Countries

Since the radical decline in mortality during this century has not been confined to the United States, it is instructive to compare our position in 1950 with the position of three other nations with low age-specific mortality rates—England

Figure 5. Death rates for the older ages: death-registration States, 1900-1950.

and Wales, the Netherlands, and New Zealand. For the age groups between 1 and 15, the death rates for the United States are about the same as those for other countries. For each succeeding age group the comparison becomes less favorable, and for the age groups from 35 to 65 years the death rate for the United States is higher than that shown for the other countries in the table. In short, the United States has advanced to a position of very favorable mortality for the young ages but not for the older ages.

As the second half of the twentieth century opens, major reductions in mortality rates must come through control of accidents and the chronic diseases. This does not necessarily require another medical revolution similar to that which occurred for the infectious diseases. The experience of other countries demonstrates that a substantially lower mortality for the older ages is possible, even at the present level of medical knowledge.

Milk Sanitation Honor Roll for 1951-52

Seventy-two communities have been added to the Public Health Service "honor roll" of safe milk communities, and 35 communities on the previous list have been dropped. This revision covers the period from January 1, 1951, to December 31, 1952, and includes a total of 239 cities and 56 counties.

Communities on the "honor roll" have complied substantially with the various items of sanitation contained in the Milk Ordinance and Code Recommended by the United States Public Health Service. The State milk sanitation authorities concerned report this compliance to the Public Health Service. The rating of 90 percent or more, which is necessary for inclusion on the list, is computed from the weighted average of the percentages of compliance. Separate lists are compiled for communities in which all market milk sold is pasteurized, and for those in which both raw milk and pasteurized milk is sold.

The recommended milk ordinance, which forms the basis for the milk

This compilation is from the Division of Sanitation of the Bureau of State Services, Public Health Service. The previous listing, with a summary of rules under which a community is included, was published in Public Health Reports, September 1952, pp. 914-916. The rating method was described in Public Health Reports 53: 1386 (1938) Reprint No. 1970.

sanitation ratings, is now in effect through voluntary adoption in 397 counties and 1,548 municipalities. The ordinance has been adopted as regulation by 34 States and 2 Territories. In 11 States and the 2 Territories it is in effect state-wide.

The ratings do not represent a complete measure of safety, but they do indicate how closely a community's milk supply conforms with the standards for grade A milk as stated in the recommended ordi-

nance. High-grade pasteurized milk is safer than high-grade raw milk because of the added protection of pasteurization. The second list, therefore, shows the percentage of pasteurized milk sold in a community which also permits the sale of raw milk.

Although semiannual publication of the list is intended to encourage communities operating under the recommended ordinance to attain and maintain a high level of enforcement of its provisions, no comparison is intended with communities operating under other milk ordinances. Some communities might be deserving of inclusion, but they cannot be listed because no arrangements have been made for determination of their ratings by the State milk sanitation authority concerned. In other cases, the ratings which were submitted have lapsed because they were over 2 years old. Still other communities, some of which may have high-grade milk supplies, have indicated no desire for rating or inclusion on this list.

Communities Awarded Milk Sanitation Ratings of 90 Percent or More, 1951-52

Note: In these communities the pasteurized market milk shows a 90-percent or more compliance with the grade A pasteurized milk requirements, and the raw market milk shows a 90-percent or more compli-

ance with the grade A raw milk communities listed. This percentage is requirements of the Milk Ordinance an important factor to consider in and Code Recommended by the estimating the safety of a city's milk United States Public Health Service supply. All milk should be pasteurized, either commercially or at home. Note particularly the percentage of milk pasteurized in the various communities before it is consumed.

Immunization Information for International Travel

A summary of the changes made in immunization requirements from May 31, 1951 through January 1953, is given in a supplement to the booklet Immunization Information for International Travel, issued in May 1951.

Additional copies of the supplement may be obtained from the Division of Foreign Quarantine. The booklet and the supplement are available to Public Health Service personnel through regular supply channels. They may be purchased from

the Superintendent of Documents, U. S. Government Printing Office, Washington 25, D. C., at 15 cents for the two. On orders of 100 or more of the supplement and booklet, delivered at the same address, a discount of 25 percent is allowed.

State and local health departments and facilities of the Public Health Service are informed of official changes in immunization requirements through "Quarantine Measures" in the weekly Communicable Disease Summary.

A Facility for Use Of Radioactive Isotopes In a General Hospital

GENERAL HOSPITALS more and more are becoming a point of use of radioactive isotopes for certain clinical tests and for treatment of selected patients. The unique characteristics of radioactive substances as employed in medical practice make necessary the planning and development of a special area to accommodate their use in the general hospital.

Based on established knowledge of the hazards associated with the use of radioactive isotopes, and on current experience in operating units, the Public Health Service, in cooperation with the Atomic Energy Commission and other authorities, has developed guide material for use in designing a radioactive isotope area in a general hospital.

Plan of the Area

The minimum, basic, adequate facility for use of radioactive isotopes in the hospital consists of two rooms: a radiochemistry laboratory and a patient uptake-measuring room (see plan on page 450).

In the radiochemistry laboratory, the shipments of radioactive isotopes are received and stored and the proper dilutions for patient dosage are prepared. Here also, clinical specimens are prepared for examination, the doses of isotopes are given to patients, and glassware, linens, clinical specimens, and other items contaminated with radioactive isotopes are cleaned,

held for decay of radioactivity, or stored prior to disposition.

The plan incorporates such elementary design features as: equipment located on the side walls, permitting window space with heating outlets below; separate work tops for patient dose and clinical specimen preparation: high level radiation area and isotope storage (see "hoods 7" and "13" on drawing) on an outside wall, far removed from radiation measurement area; separation from patient uptake-measuring room by a corridor to minimize disturbance of radiation measurements caused by storage of stock solutions of radioactive isotopes.

In the patient uptake-measuring room, the radioactive content of clinical specimens is determined and the patient uptake of radioactive substance is measured. The room is divided into three areas: waiting, clerical, and clinical.

This basic, 2-room facility should provide for a patient load of about 60 patients a month. On the assumption that not more than 2 or 3 patients are receiving radioactive gold-198, it is equipped for a maximum of 10 patients in a working day.

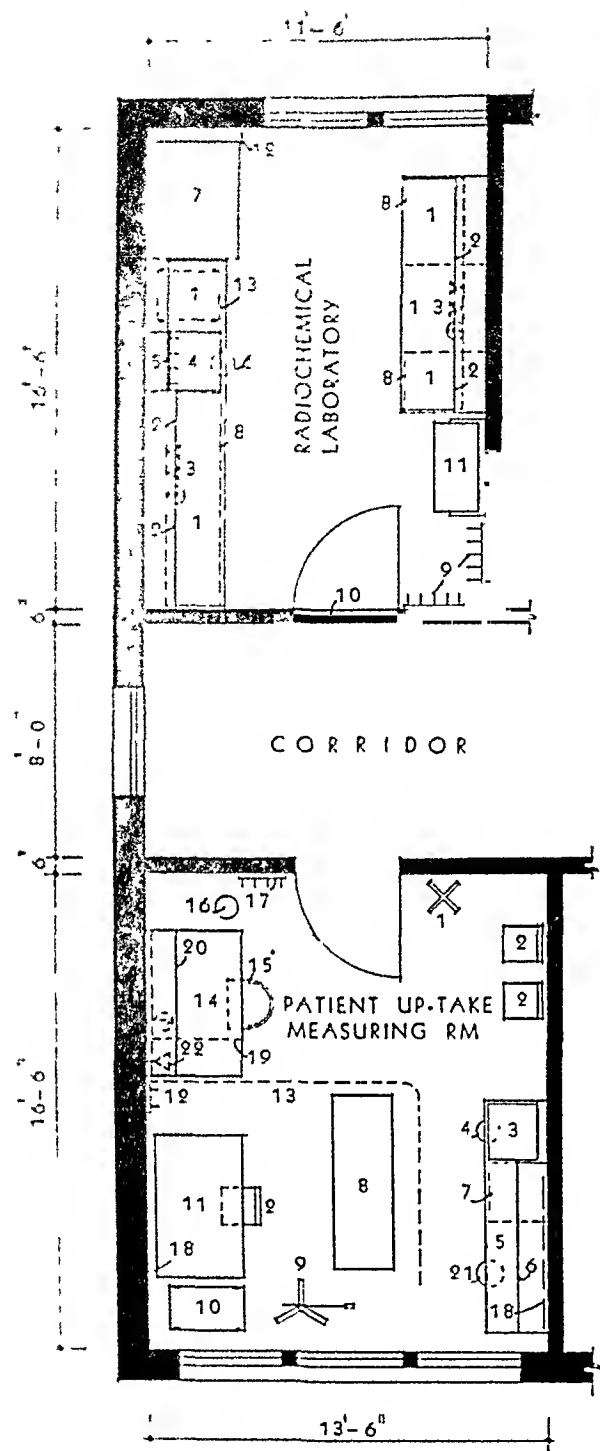

As the use of radioactive isotopes will probably increase, the hospital should plan for economical expansion of the isotope area. By adding a second patient uptake-measuring room, the hospital can double the patient capacity of this basic facility.

Design and Operation

Design and construction of the radioactive isotope area must provide for necessary radiation shielding to maintain personnel exposures below 0.3 roentgen a week, for preparation of patient doses of isotopes, for ease of cleanup whenever radioactive material is accidentally spilled, and for measurement of the patient's absorption of isotopes.

In operating radioactive isotope facilities, continued vigilance is necessary to protect personnel against excessive radiation exposures and to assure that work areas are free from contamination. Personnel exposures should be monitored by use of film badges or pocket radiation dosimeters to be worn at all times the individual is in the area. Work areas should be

The guide material was developed by W. R. Taylor, hospital architect, Division of Hospital Facilities, and Samuel C. Ingraham, M. D., Division of Engineering Resources, Public Health Service. Technical details are given in the December 1952 issues of Hospitals (p. 74) and Architectural Record (p. 181).

Radiochemical Laboratory

1. Work top with splash back.
2. Wall cabinets.
3. Air, gas, and electric outlets.
4. Sink, foot, knee, or elbow controls for hot and cold water, plus one cold-water hand-controlled outlet.
5. Peg board.
6. Contaminated waste receptacle under sink.
7. Fume hood.
8. Cabinets below.
9. Hook strip.
10. Bright yellow flush threshold to indicate radiation hazard zone.
11. Paper-roll holder 48 inches above floor.
12. Metal closure plate.
13. Isotope storage below work top, on dolly.

Patient Uptake-Measuring Room

1. Costumer.
2. Straight chair.
3. Sink, foot, knee, or elbow controls.
4. Contaminated waste receptacle.
5. Work top.
6. Wall cabinets.
7. Cabinet below work top 24 inches wide.
8. Examination table.
9. Tube stand on casters.
10. Dolly.
11. Table.
12. Hook strip for patients' clothes.
13. Curtain rod and curtain.
14. Stenographer's desk.
15. Stenographer's chair.
16. Waste paper receptacle.
17. Hook strip for staff.
18. Constant voltage plug-in strip.
19. Record file.
20. Book shelf above desk.
21. Stool.
22. Telephone outlet.

monitored regularly by use of radiation survey instruments suitable for detecting possible contamination of furniture, walls, and floors.

Hospitals planning the use of radioactive isotopes for the first time should consult the

Isotopes Division of the Atomic Energy Commission, Oak Ridge, Tenn., to learn the requirements and regulations governing qualification for use of radioactive isotopes for human applications.

Organized Health Services in A County of the United States

Several years ago a cooperative project was undertaken by the Monongalia County Health Department in West Virginia and the Public Health Service to survey the structure and function of all organized health services having an impact on the people of one rural county. It was the first such study made. The report was mimeographed and had limited distribution, but demand for it was great so it was printed in this present form.

The report covers in detail all agencies in the county which provide health services, types of service and administrative structure of each, source of support of their operations, and extent of service. The scope of activity includes preventive disease services, medical care, and research and training. The summary and discussion considers the historical backgrounds, local-State-national relationships, and the role of the health department.

At the end of January 1949, there were in Monongalia County 155 different agencies with organized health services. These agencies fall into the general categories: official and voluntary health agencies, other official agencies with health functions, voluntary social agencies with health functions, health service enterprises, health functions of industry and labor, professional and auxiliary organizations, and civil and social groups with health functions. The largest number of these agencies was supported by tax funds and the next largest group by individual members.

An analysis of the quantitative data in the report indicates that far greater sums were spent on medical care than on prevention of disease. Individual categorical programs, such as services for veterans, workmen's compensation cases, or sanatorium care for tuberculosis, involved greater expenditures than the

entire appropriation for the county health department from all local sources.

Official health agencies were responsible for the greatest volume of services and expenditures relating to prevention of disease, and other official health agencies with health functions had a large share in school health services, safety, food and drug control, nutrition, and industrial and adult health. Voluntary agencies played a major role in tuberculosis and chronic disease control, and in health education. Of the medical care programs, the largest in the county were those for company employees covered by prepayment plans, especially miners and their dependents, and those for veterans. Organized efforts for hospitalization have been greatest for special classes of service under the medical care programs. The greatest financial weight of the special illnesses has been for tuberculosis.

Services of the programs for preventive disease and medical care under government agencies tended to exceed those provided by the voluntary agencies, particularly those for crippled children. On the other hand, in many spheres of health and community activity in which government has not participated, those of the voluntary agencies and economic enterprises were of the greatest significance.

Tuberculosis Beds in Hospitals and Sanatoria January 1, 1952

There are in the United States and Territories 1,122 institutions which provide 111,505 beds for the care of tuberculosis, according to the seventh annual edition of the *Index of Hospitals and Sanatoria with Tuberculosis Beds in the United States and Territories*. Of these, 1,006 hospitals are local (State, city, county, and district), and 116 are

operated by the Federal Government. In the continental United States alone there are 1,097 institutions, 982 of which are locally operated and 115, federally operated.

Comparison with the 1951 index reveals that 373 institutions previously unreported appear in the latest edition of this report. Only 7 of these are new facilities. Also, 26 institutions which were reported in the earlier index are deleted from the present edition and reasons for these deletions given.

The information in the 1952 index was gathered by means of a post-card questionnaire sent to all the locally operated hospitals. Data are analyzed as to type of hospital and ownership and control, and are compared with data in the 1951 report. The hospitals are indexed by State, with the number of beds given for each institution.

The Head Nurse Looks at Her Job

The continuing shortage of nurses is one of the most acute problems in medical care today. Even the most successful recruitment programs cannot supply graduate nurses fast enough to keep pace with the demands for their services. These factors indicate a need for hospitals to evaluate the utilization of professional nursing personnel and to determine whether or not administrative changes might save personnel time and hospital dollars.

This manual, developed by the Division of Nursing Resources of the Public Health Service, offers a method by which hospitals of all sizes may determine how head nurse time is distributed between patient care management duties and duties which could be performed by less skilled nursing personnel. It was developed for use in units providing

1-to-100 care to patients in general and allied special hospitals.

The method described consists of observations of head nurse activities in one or more units for a period of two or more full days during which detailed time records are kept. An observer "shadows" the head nurse and assistant head nurse at all times while they are on duty and records the time, the area of activity and the level of skill required for each task performed. The recorded data are coded according to area and level and later tabulated and analyzed for use in determining what corrective action may be needed and how to initiate it.

The manual outlines the procedures for such a study and is in loose-leaf format to facilitate its use during the training period before a study as well as during the study itself. Detailed instructions are given for observers, including the classification of activity areas and levels. Suggestions are given for constructing the record forms and the manner in which data are to be recorded and analyzed. The appendix also includes two training narratives to assist in the teaching of observers.

For the general public

Arthritis and Rheumatism

Arthritis is man's oldest known chronic affliction and is the world's leadingcrippler. About 7½ million Americans suffer from arthritis and rheumatism, and 1 million of those are permanently disabled. The prevalent forms of these diseases—rheumatoid arthritis, osteoarthritis, rheumatic fever, gout, and fibrositis—are discussed in this health information leaflet. The information also includes suspected causes,

symptoms, effect on various parts of the body, and treatment.

Readers are warned against self-treatment. They are urged to seek a physician's advice if suffering pain, stiffness, or swelling in the joints, for early treatment by a physician benefits the majority of rheumatic patients and often prevents disability.

Attention is called to the work of three organizations on arthritis and rheumatism. The American Rheumatism Association, the Arthritis and Rheumatism Foundation, and the National Institute of Arthritis and Metabolic Diseases of the Public Health Service are working co-operatively to increase the understanding and improve the treatment of arthritis and rheumatism.

• • •

Arthritis and Rheumatism. Health Information Series, No. 9 (Public Health Service Publication No. 29) revised 1952. 2-fold leaflet. 5 cents; \$2 per 100 copies.

Importance of Nutrition To Good Health

This leaflet was prepared in response to frequent requests for nutrition information which could not be satisfactorily referred to other Federal agencies. The introduction stresses the importance of good nutrition for good health and the need for proper diet to prevent fatigue at work and play and to avoid lowered resistance to infection. A physician's advice is suggested if a special diet is needed.

The leaflet describes the important food elements, and how they are used in the body. Foods containing the various elements are listed in the margins of the pages. The vitamins are discussed in the same manner, with a description of each, what it does for the body, and the foods in which it is found. A brief section on calories is included. Reference is made to a chart showing food values and calories, obtainable from the U. S. Department of Agriculture, and to other source material.

Importance of Nutrition to Good Health. Health Information Se-

ries No. 31 (Public Health Service Publication No. 162) 1952. 12 pages; illustrated. 5 cents. \$3.75 per 100.

Diabetes

About 2 persons out of every 100 have diabetes mellitus, according to recent surveys, and about half of them do not know they have it. The disease can develop in persons from all age groups, but those over 40, those with diabetes in their families, and those who are overweight are most likely to have it.

These facts are brought out in this health information leaflet which discusses diabetes, its cause, and the manner in which it is controlled. The functions of the pancreas, the results of its malfunctioning, and the symptoms of diabetes are described. The information given also includes the tests by which the disease can be detected and the methods of controlling it through the use of bottled insulin, dietary restrictions, and proper exercise. It is pointed out that because of the increasing numbers of persons over 45, diabetes is more common than formerly. However, since it can be discovered and treated successfully, no one need be handicapped by diabetes.

Poliomyelitis Distribution in the United States

By ROBERT E. SERFLING, Ph.D., and IDA L. SHERMAN, M.S.

IN THE EARLY summer of 1894 inhabitants of the Otter Creek Valley in western Vermont became aware of a strange paralytic disease in their community. It seemed to select younger children as particular victims although a few adults were also affected. This first notable epidemic of poliomyelitis in the United States was carefully investigated by Dr. C. S. Caverly, president, Vermont State Board of Health. His field studies, constituting a classic model of "shoe-leather" epidemiology, mark the beginning of our modern knowledge of poliomyelitis. In the following years other investigations conducted in the Caverly pattern demonstrated the extensive distribution of the disease and indicated the need for systematic morbidity reporting.

Massachusetts, in 1907, was the first State (1) to require notification of all cases of poliomyelitis. In 1910, the Surgeon General of the Public Health Service requested all States to submit reports on poliomyelitis for 1909 and 1910. This initiated national reporting of poliomyelitis, although regular inclusion of reports from all States was not achieved until about 1922. Since that time a large body of data has accumulated, forming an increasingly comprehensive base for continuing analyses of elementary epidemiological characteristics, such as secular trends, geographic distribution, and seasonal variation. A number of excellent analyses have been published (2, 3, 4, 5), but

the most recent include only the years through 1946 in the United States (6, 7). Sabin (8) reviewed epidemiological characteristics of a number of poliomyelitis outbreaks throughout the world.

Certain epidemiological characteristics of poliomyelitis have changed with time. In the United States, annual rates both of reported cases and of deaths have shown an upward trend, particularly during the past decade. In earlier decades a lower incidence was observed in southern States than in northern States. This difference is less apparent in recent years.

Continuing studies and analysis of these elementary epidemiological characteristics and their changes are indicated for any infectious disease that remains as a serious problem in the country. Furthermore, discovery of the value of gamma globulin in the prophylaxis of poliomyelitis (9, 10) poses difficult problems as to the best way to utilize available supplies.

The fullest possible knowledge of the current epidemiological pattern of poliomyelitis as revealed by morbidity and mortality reports may be useful in guiding administrative decisions. For these reasons the present paper has been prepared. The past history of poliomyelitis as recorded in published literature and official reports was reviewed and special attention was given the period 1932 to 1952 with particular emphasis on changing patterns of the past 5 to 10 years.

Dr. Serfling and Mrs. Sherman are chief and assistant chief, respectively, of the statistics section, epidemiology branch, Communicable Disease Center, Public Health Service, Atlanta, Ga.

National Incidence

The trend of the national case and death rates in the United States during the period 1910-52, is shown in figure 1. Since both cases and

death were not reported from the same group of States during earlier years, the rates in figure 1 were based on reports from those States which reported both cases and deaths. The record of national incidence of poliomyelitis in the United States falls naturally into four periods:

1. Prior to 1909, when information on incidence, except for a few States, depended on descriptive accounts in the epidemiological literature.

2. From 1909-16, when published reports were available from some States. These were supplemented by special studies of Lavinder, Freeman, and Frost, and their summaries give more complete information on the period.

3. From 1917 through the epidemic year 1931, during which time reporting gradually became more complete. By the middle 1920's most States were reporting annually.

4. From 1932 until the present, during which time national reporting of both cases and deaths has been essentially complete. Because of the obvious differences which characterize national reporting in the different periods, they are presented separately in this discussion.

Early Years

During the 1894 outbreak in Vermont, Caverly collected information on 132 cases. Of these, 119 had shown paralysis, 7 had died before paralysis was noted, and 6, although exhibiting symptoms characteristic of early stages of the illness, had not developed paralysis. In Rutland, the largest community in the affected area, 55 of the 12,000 inhabitants had been stricken—an attack rate of 460 cases per 100,000 population. In nearby Proctor, a town of 2,000 persons, 27 cases had occurred. The remaining 50 cases were scattered through a dozen small communities in the area.

Two years later, in a final report of his investigations (11), Caverly concluded that the disease was "epidemic poliomyelitis," possibly a variant form of the "infantile paralysis" which in the United States had been known principally as an endemic disease of relatively infrequent occurrence.

In the succeeding years similar outbreaks occurred with increasing frequency in many parts of the country. In 1908 two papers (12, 13)

summarized accounts of 17 poliomyelitis epidemics in the United States and others throughout the world. By this time, outbreaks had been described in Alabama, California, Florida, Illinois, Maine, Massachusetts, Michigan, Missouri, New York, Pennsylvania, and Wisconsin. These seem generally to have been of smaller scale than the Rutland episode.

In New York City, however, the 1907 outbreak was the largest then recorded in any place. The impact led to an extensive retrospective investigation initiated in October of 1907. The study (14) was conducted by mail and produced detailed information on 752 cases. It was estimated that in all, about 2,500 cases had occurred. Although cases were somewhat concentrated on the east side of Manhattan, the epidemic had extended northward to Poughkeepsie and throughout the western end of Long Island. The case fatality was estimated to be 5-7 percent, about half that of the Rutland outbreak.

In Massachusetts, where smaller outbreaks had been noticed since 1893, incidence was also high in 1907 and the State made poliomyelitis a reportable disease. In 1908, 136 cases were reported in Massachusetts (1). In midwestern Minnesota, 150 cases were recorded, and in Wisconsin, 408. In the following year, 1909, a great outbreak struck in Nebraska. Description of this epidemic (15) was also based on a retrospective study. In answers to letters, 58 physicians reported 999 cases in 18 counties. The greatest number of cases, 384, was reported from Polk County, with a population of 10,000. Douglas County (1910 population, 168,546) reported 79 cases, a rate slightly less than 50 per 100,000 population, and comparable to that of the New York City epidemic of 1907. In 1910 Massachusetts reported 845 cases, Pennsylvania 1,112, and in the midwest, Minnesota and Iowa each recorded more than 600 cases. In the far west, nearly 400 cases occurred in the State of Washington. On August 9 of that year (1910) the Surgeon General of the Public Health Service initiated the request that started national reporting of poliomyelitis. In the same year provision was also made for separate classification of poliomyelitis deaths in the national vital statistics summary.

Figure 1. Annual poliomyelitis case and death rates in States reporting both cases and deaths, United States, 1910-52.

SOURCES: Cases, 1910-50—Public Health Service: The Notifiable Diseases (Pub. Health Rep. Supp.). 1951—National Office of Vital Statistics: Reported Incidence of Notifiable Diseases in the United States, 1951, Annual Supplement to Weekly Morbidity Report, vol. 2, No. 53, 1953. 1952—National Office of Vital Statistics: Morbidity and Mortality Weekly Report, vol. 1, Nos. 1-53 inclusive. Deaths, 1910-49, Vital Statistics of the United States. U. S. Bureau of the Census, 1910-44; U. S. Public Health Service 1945-49. 1950-51 data from advance releases, 1952 data from 10 percent mortality sample, Jan.-Nov., National Office of Vital Statistics.

For 1909 only 3 States submitted morbidity report- to the Public Health Service and in the following 7 years the numbers ranged from 11 to 29. After the 1916 epidemic, Lavinder, Freeman, and Frost published a summary of morbidity and mortality for the period 1909-16 which incorporated data from a number of States not included in the earlier national summaries. For the years 1909-15, they obtained additional State morbidity reports and also mortality reports for some States in which no morbidity data were available. For the latter, estimates of cases were made from reported poliomyelitis deaths, assuming a case fatality rate of 20 percent. For States in which only certain cities were in the registration area, deaths for the entire State were estimated from those in the registration areas. Since Lavinder, Freeman, and Frost had noted that in States for which registration was complete, the urban death rate was lower than the rural rate and that a case fatality as high as 20 percent occurred only rarely, they believed that error in their estimates had been in the direction of underestimation. Because of the care which went into this study, their figures for annual incidence of poliomyelitis in the Nation for 1909-16 are quoted below:

Year	Cases per 100,000 population
1909	6.9
1910	13.3
1911	9.5
1912	8.5
1913	6.6
1914	5.1
1915	5.1
1916	28.5

During the 5 years following the 1910 outbreaks, the estimated national rates declined. In these years the largest outbreaks took place in 1912, when New York reported 1,108 cases and California, 531. These were the only instances in which a State reported more than 500 cases, although Massachusetts, New York, Pennsylvania, and Virginia reported from 100 to 500 cases annually, and Illinois and Ohio reported from 100 to 500 cases in 4 of the 5 years.

The great epidemic of 1916, although leading to highest rates in the northeastern States, also

Table 1. States reporting 20 or more poliomyelitis cases per 100,000 population in 1916

struck severely in the north central area and in Montana. States with rates of approximately 20 per 100,000 population or larger are listed in table 1.

For the year 1916, Lavinder, Freeman, and Frost obtained morbidity reports from all but four States, amounting to a total of 29,061 cases. From these they estimated the national rate to have been 28.5 cases per 100,000 population.

¹ Includes District of Columbia as a separate reporting unit. States reporting cases not necessarily the same as those reporting deaths.

SOURCES: Cases, Notifiable Diseases, Annual Reports, Public Health Service; Deaths, Death-Registration States, Annual Reports, Vital Statistics of the United States.

The total number of cases in the District of Columbia and the 27 States which reported to the Public Health Service was 27,363. Among these States, the average rate was 41 cases per 100,000 population.

Years 1917-31

After 1916, no additional efforts were made to obtain complete information on reported cases of poliomyelitis. Annual case rates for the Nation, computed on the basis of the populations of those States submitting reports, and death rates for the death-registration States are shown in table 2. The period seems to have been one of generally low incidence of poliomyelitis. National rates varied from 2.0 in 1922 to 8.8 in 1927, except for the epidemic year of 1931, when the rate reached 12.8. Despite the generally low national rates, outbreaks of moderate size were reported by a number of States.

In 1917, the rate in Vermont was three times the 1916 rate. In the early and middle 1920's, the north central and western States of Minnesota, North Dakota, Montana, and Washington reported the highest rates in the country. In 1927 and 1928 a dozen States, ranging from Maine to California, reported from 21 to 49 cases per 100,000 population. The 1931 outbreak was largely concentrated in the New England and Middle Atlantic States, and in Michigan in the midwest. The highest rates occurred in Connecticut (69.6) and in New York (48.2).

Years 1932-52

Annual rates for the United States during the period 1932-52 are shown in table 3. After the 1931 outbreak, the annual national rates did not exceed 10 cases per 100,000 population until 1944. In 1943 the case rate was 9.3, the highest since 1931, and in the succeeding years rose to successively higher levels, until in 1952 both the case rate (36.9) and the estimated death rate (2.0) were higher than in any year since the 1916 epidemic. With the marked upward trend in the morbidity rate, there has been a slight but definite increase in the mortality rate. This has resulted in a progressive decline in the ratio of reported deaths to cases from 14.0 percent in the period 1932-36 to 5.8 percent in the period 1947-51.

¹ Case and death rates based on population of States reporting both cases and deaths.

² 1952 death rate estimated from 10-percent national sample of the National Office of Vital Statistics, January through November 1952.

The morbidity rate for 1952 falls between the two estimates (see above) for 1916, while the estimated mortality rate for 1952 is only one-fifth as great as the 1916 death rate of 10.5 per 100,000. The question of whether or not the 1952 epidemic was more severe than that of 1916 is obscured by several factors relating to the population bases used in determining the rates. In 1952 reports of cases and deaths were available from all States, whereas for 1916 two estimates of the morbidity rate are available, but neither of the populations on which these are based is the same as that of the 26 death-registration States for which the mortality rate was 10.5 per 100,000. Also, the 1916 population of the death-registration States coincided closely with the populations severely affected by the epidemic, while the 1952 estimated death rate of 2.0 per 100,000 includes populations not in epidemic areas. In addition to these factors,

Figure 2. Poliomyelitis morbidity—average 5-year rates, major geographic divisions of the United States, 1932-36, 1937-41, 1942-46, 1947-51.

others must be considered: for example, improvement in completeness and accuracy of morbidity reporting; and improvement in treatment, presumably resulting in lowered case fatality rates.

Geographic Distribution

The geographic distribution of poliomyelitis in the United States during the last 20 years is described for the nine major geographic divisions of the country from two approaches: average incidence in successive 5-year periods and variation in annual incidence. Each method gives emphasis to different aspects of secular changes in geographic distribution of the disease.

Average Incidence

Aycock (3), in studying distribution of poliomyelitis in the United States during the period 1910-27, and later Wells (4), in a study of the period 1915-29, came to the conclusion that incidence in the northern States had been distinctly greater than that in the southern

portion of the country. Both of these studies included the 1916 epidemic, which caused the average rates to be heavily weighted by this single northern epidemic. Collins (5), examining data for the period 1930-45 noted that little poliomyelitis had been reported from the three southern divisions prior to 1935 but that subsequently they experienced "some rather large epidemics." Gilliam, Hemphill, and Gerende (6, 7), in a study of county rates during the period 1932-46, came to a similar conclusion. In their study, the average annual rate in the period 1932-46 for northern counties was 7.6 and for southern counties, 6.4. However, in large urban counties of over 500,000 population, average rates were lower in northern than in southern counties. In counties under 100,000 population, the reverse was true—the average rates were higher in northern than in southern counties. The period was one of generally low incidence, except for the later years, 1944-46. In the present study, examination of rates for the 20 years 1932-51, in successive 5-year periods, did not seem to reflect consistent geographic localization (fig. 2).

During the first 10 years (1932-41) of the period, average incidence was remarkably uniform over 5 of the 9 major geographic divisions (table 4) ranging from 5.1 to 5.9 per 100,000 population. One of these five was the East South Central division. The lowest rates occurred in the West South Central and South Atlantic States (3.0 and 4.6); the highest rates occurred in the Mountain and Pacific divisions (6.3 and 10.7).

During the first half (1942-46) of the next decade, the northwestern divisions had rates which were generally higher than those of the South Atlantic, East South Central, and West South Central divisions. However, within the eastern and southern regions, the average 5-year rates for the New England States was somewhat lower than that of the West South Central States.

In the next 5 years (1947-51), a different configuration was displayed, the divisions west of the Mississippi having rates considerably higher than those east of the Mississippi. Average 5-year rates were nearly the same, 13.4, 14.0, 14.1, and 14.5 per 100,000 respectively, in the East South Central, South Atlantic, New England, and Middle Atlantic States. In intermediate position were the East North Central and West South Central States with average rates of 20.4 and 22.2 per 100,000 population.

The West North Central, Mountain, and Pacific States, with average 5-year rates, respec-

tively, of 28.5, 28.5, and 26.1, were markedly higher than the rest of the country. For individual States, 5-year average rates are shown in table 5. It should be noted that the 5-year average rates varied considerably among the States in each division.

Over the past 20 years geographic differentials in incidence between regions of the United States have existed. In the long run, these differentials have tended to become equalized, although over rather extended time periods. Over moderate periods of time, one region may experience severe epidemics alternating with periods of very low incidence, while another region may be experiencing a succession of epidemics. As a result, even longtime averages are greatly influenced by a few severe epidemic years.

The average 20-year rates for western geographic divisions, which depart most from average rates of the remainder of the country, have been greatly influenced by the experience of recent years. The marked recent rise in the western States generally, and particularly, in the southwest, suggests that it may be of interest to watch the future trend in the southeastern States which have recently had only moderate increases in their annual rates.

Changing Epidemic Patterns

Interpretation of geographic differences calls for consideration not only of average incidence,

Table 4. Average poliomyelitis case rates in each division of the United States, 1932-51, by 5-year, 10-year and 20-year periods¹

¹ Average numbers of cases per 100,000 population based on annual reports in *Notifiable Diseases*, Public Health Service.

Figure 3. Poliomyelitis morbidity in major geographic divisions of the United States, reported cases per 100,000 population per annum, 1932-52.

but also of shifting centers of epidemic concentration. Configurations of States swept by epidemics change from year to year as the areas of greatest incidence move from one region to another. Regions swept by an epidemic at one time dissolve into components which re-form in new configurations as a succeeding epidemic wave develops.

The annual concentrations of epidemics have been illustrated excellently in the series of maps prepared for many years by Dr. Carl C. Dauer. The first maps in this series were published in *Public Health Reports* (16) and included the years 1933-37. For subsequent years the maps have been published yearly in an annual review of reported poliomyelitis in the United States. The changing centers of epidemic concentration illustrated in detail in Dauer's series of maps can also be recognized in the annual poliomyelitis rates (fig. 3 and table 6) for each division of the United States.

From 1932 through 1939, three distinctive patterns of epidemic outbreaks emerge: The Mountain and Pacific States, which experienced their most severe outbreak in 1934; the New England, Middle Atlantic, and South Atlantic States in 1935; the East South Central States in 1936 and 1937; and the remaining three central divisions in 1937.

From 1940 through 1948, severe epidemics did not strike east and west of the Mississippi in the same years, except for States in the East North Central division, which experienced epidemics coincident in some years with States east of the Mississippi; in other years, with western States. In 1944, the East North Central States reflected the eastern epidemic; and in 1946, the western outbreak.

In 1949, all divisions except the South Atlantic experienced severe outbreaks of poliomyelitis. In the latter division, 1948 and 1950 were years of greater severity. In 1950, rates were moderately high in all areas.

In 1951, the national rate was lower than in the preceding 3 years. The highest rate was recorded in the Mountain division. In the severe epidemic of 1952, a record rate of 98.0 occurred in the West North Central States. Record rates were also reported from the other three central divisions and from the Mountain

States. The Pacific division experienced the third highest rate in its history. Along the eastern seaboard rates were well below the national average, although moderately high in comparison with many previous years.

Seasonal Distribution

If the reported cases of poliomyelitis in the United States for each month are averaged for a few years, the resulting curve rises slightly in

Table 7. Seasonal incidence of poliomyelitis, United States, 1942-52

[Reported cases per 100,000 population, each month, adjusted to annual base]

Figure 4. Poliomyelitis morbidity, seasonal incidence, United States, rates by month, each year, 1942-52.

May, more rapidly in June and July, and reaches a maximum elevation in August and September. In October there is a marked decline which continues through succeeding months. In some years (fig. 4, table 7), August is the month of maximum incidence; in others, September; but in some, the attack rate has been

approximately the same in both months, for example, the years 1944 and 1951. In two recent years, 1950 and 1952, the October rate has been relatively higher than in earlier years.

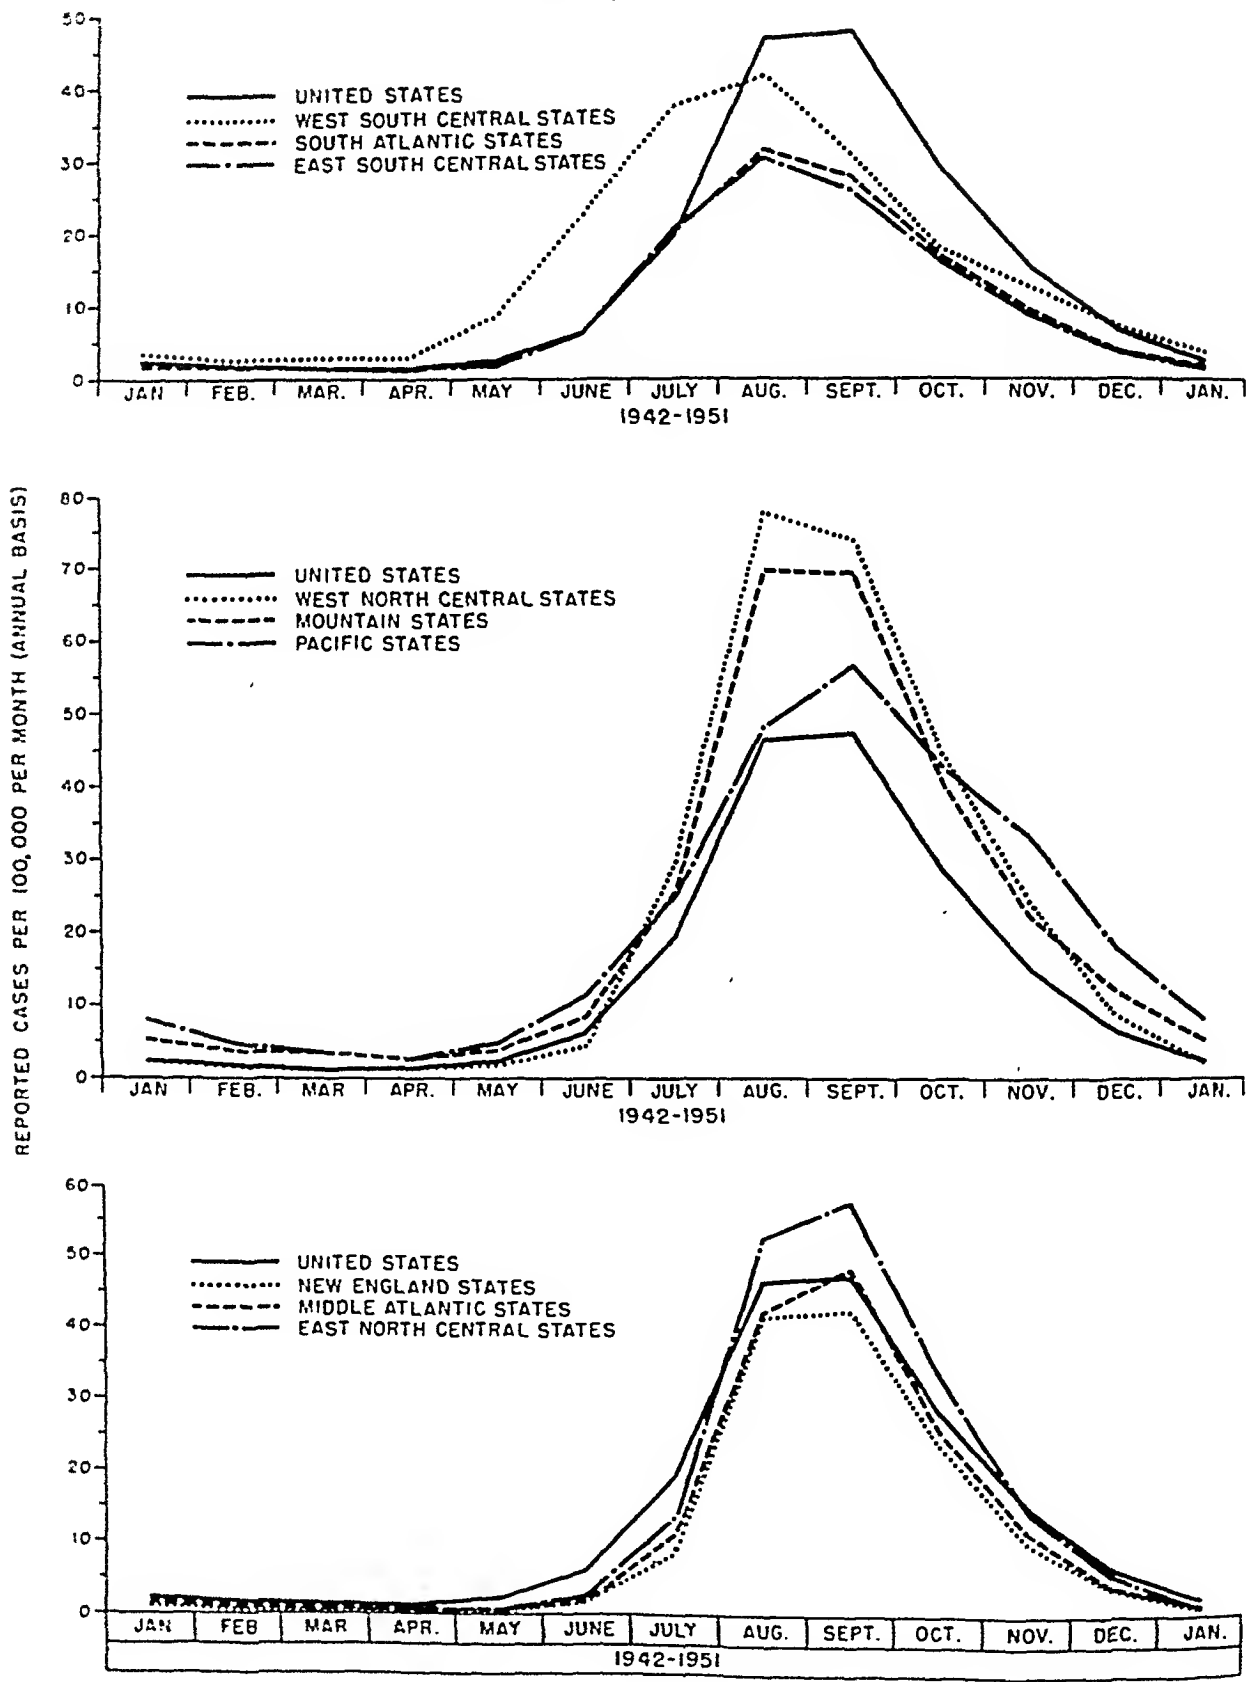

The seasonal change in incidence differs from one region of the United States to another (fig. 5, table 8) and these differences are re-

Figure 5. Poliomyelitis morbidity, seasonal incidence, 10-year average rates by major geographic divisions, 1942-51.

flected in the national curve of seasonal incidence as the center of epidemic intensity year-to-year moves from one area to another.

In the southern divisions of the United States, the initial rise occurs in May, reaching a maximum level in August; in the central and Pacific States, the rise begins in June and the high levels occur in August and September; and in the northeastern divisions the rise is not appreciable until July, and the highest average rates are observed in September. Generally, the epidemic span is shorter, with rise and fall more rapid, in northern latitudes.

Seasonal concentration of cases during a short epidemic period has been characteristic of the New England, Middle Atlantic, and East North Central States. In these divisions (table 9), 60 percent of the year's cases, on the average, have been reported during August and September. In the West North Central and Mountain divisions, concentration in these months has been similar but somewhat less pronounced. In these divisions, 50 to 55 percent of the total annual number of cases were reported during August and September in 1942-51.

In the South Atlantic, East South Central, and West South Central divisions, concentration in August and September has been less noticeable. Approximately 60 percent of the year's cases, on the average, were reported during July, August, and September. In the

Pacific States, extension of the season of higher incidence into the fall months has been noticeable; 40 percent of the annual total cases, on the average, having been reported during August and September, and another 30 percent of the annual totals, during October and November.

Summary

Early descriptive accounts of poliomyelitis outbreaks in the United States have been reviewed and an analysis made of State morbidity reports since 1907.

Poliomyelitis, a comparatively rare disease in the early years of this century, has since been recognized as a communicable disease problem in every State in the Nation. During the last 20 years the trend of the annual case rate has been upward, particularly during the last decade, during which a marked increase has occurred. The death rate has shown a slight but definite increase. In 1952, for the Nation, both the case rate and the estimated death rate were the highest since the 1916 epidemic. The ratio of reported deaths to reported cases has decreased over the last 20 years.

Earlier observers noticed that rates had been higher in the northern than in the southern regions of the country. In recent years this difference has diminished and an East-West differential is more prominent. In recent years both average and maximum rates have been

Table 9. Seasonal incidence of poliomyelitis in major geographic divisions; number of cases per month expressed as percentage of total cases, 10-year average, 1942-51

Divisions	January	February	March	April	May	June	July	August	September	October	November	December	Total

Mountain.....	1.9	1.2	1.3	.9	1.5	3.1	9.8	26.6	25.6	15.4	8.2	4.6	100.1
Pacific.....	3.1	1.7	1.3	1.0	1.9	4.3	10.0	18.8	21.5	16.8	12.6	7.0	100.0
United States.....	1.3	.9	.8	.7	1.3	3.4	11.1	26.4	26.0	16.1	8.3	3.7	100.0

higher in the western and north central division of the United States than in the northern and southeastern divisions. Over extended periods of time geographic concentration has not been consistent.

In southern regions of the country, seasonal rise in incidence occurs earlier and the epidemic span is longer than in the northern regions.

Type I Poliomyelitis Virus Adapted to Mice

Successful adaptation of type I (Mahoney) poliomyelitis virus to Swiss mice has been achieved by Drs. C. P. Li and Morris Schaeffer of the Public Health Service Communicable Disease Center. Their report appears in the March 1953 issue of the Proceedings of the Society of Experimental Biology and Medicine, pages 477-481.

The authors conclude that: "The use of the intraspinal route of inoculation and the selection of a mutant or variant of the virus is believed to be responsible for this adaptation. . . . With this attainment, all three poliomyelitis virus types have now been adapted to mice. This will permit for rapid progress in field and laboratory studies of poliomyelitis." The findings are important to poliomyelitis diagnosis and to the development of a live virus vaccine.

Public Health Operating Statistics

By ROBERT G. WEBSTER, M.P.H.

"GOLD THAT BUYS health can never be ill spent." Thus, in 1603, John Webster, Elizabethan poet and dramatist, gave expression to an opinion which later centuries have proved correct. The dividends of investments in health were never greater than they are today.

But today we must be prepared for a tightening of the purse strings. The cost of war or its prevention, estimated at over 75 percent of the total Federal budget (1), may have seriously threatened the future of the grants-in-aid fiscal program supported by the Congress. The nearness of the saturation point in the potential for tax collections in State and local governments indicates the need for better justification of public health programs, if increased support is to be expected from this source.

The generosity of the American people has made it possible for many voluntary organizations to make significant contributions to public health. Increasing efforts are required to collect such funds, and the number of voluntary groups competing for the beneficence of the public multiplies the problem of financing public health. If appropriating bodies are asked to provide adequate funds, public health agencies must provide standards for evaluation against which the funds requested may be measured. We should, therefore, thoughtfully consider the use of statistics to measure the costs of public health.

Robert G. Webster, M.P.H., is chief of the division of administration of the California State Department of Public Health. This paper was presented at the 2d Conference on Public Health Statistics at the University of Michigan on June 17, 1952.

Financial Evaluation

Historically, the total gross cost of a unit of government was simply the total of the budgetary column. While this figure has some use as a general indication of the division of expenditures among the large areas of government service, more detail is needed to study the specific costs of a public health program. The recognition of a problem and the desire to do something about it are seldom sufficient in themselves to justify the grant of funds from the public treasury.

The use of statistics in building a vivid accounting picture of the operations of an agency well justifies the existence of a statistical service. Such an application of statistics gives real body to the substantiation and need for the statistical unit and presents opportunity for a realistic use of quantitative measurements in a situation where realism might be overlooked.

Service Records

"Service statistics in public health are numerical measurements of services rendered to individuals and to the community through public health programs" (2). Service statistics are a measurement of activity in terms of number of units rather than in terms of dollars.

Service, operating, or performance statistics have real value in the analysis of public health programs. They serve as guides for the administration, for the measurement, and for the evaluation of activities, and for planning. It should not be overlooked, however, that service statistics, to serve their full purpose, should be related as far as practical to specific public health problems—the problems of population, water

supply, sanitation, morbidity, mortality, and other factors.

Screening surveys, one of the newer activities in the public health field, furnish practical records in the fields of tuberculosis, venereal disease, and chronic disease. Operating records of these surveys often indicate the number of suspects found, suspects referred for medical followup, referrals completed, and the active or positive diagnoses resulting from the screening program. Statistics as to the number of persons screened are, of course, basic.

Records of persons immunized for diphtheria, pertussis, tetanus, smallpox, typhus, typhoid, or other diseases are another measure of the progressiveness and the activity of a public health agency. Such statistics usually are maintained by age groups. Often a separate tabulation is made of booster shots given.

The service records in communicable disease may be generally classified as records in the area of case finding and records related to control and service. The number of individuals X-rayed or the number of X-ray films used is an example of the case-finding statistic.

In the tuberculosis field, a tabulation of the number of tuberculosis contacts investigated becomes an evaluation of the case-finding activities. The number of laboratory tests made are of interest, too.

For control of service activities, it is helpful to compile a record of the clinic hours during which the clinic operates. This serves not only as an evaluation of the use of time, but it also indicates the availability of the service. The number of visits made to a clinic is the most frequently compiled operating statistic. More important, and more difficult, is the count of individuals admitted to a clinic which gives an opportunity for the evaluation of clinic coverage, rather than of only the clinic traffic.

Applicable to most public health programs is the tabulation of field visits or home visits. It cannot be overlooked in any cost study since in many activities a large proportion of the time is spent in home calls.

Operating records may be compiled in health education, although they are not always significant. The number of public health films shown and the number of people viewing them are tabulations which may be obtained with a min-

imum of effort. Knowing the number of different training courses offered and the number of people exposed to such courses leads to an evaluation of a direct training enterprise. The number of pieces of printed material which are distributed is in itself not too meaningful, but a record of how many people read such literature, and of whether they are stimulated to seek health services, could be.

The obvious service statistics in the laboratory field are the number of various tests which are made. Upon refinement, such records will indicate test results in statistical form. An index to the efficiency of collection procedures and techniques is the number of specimens examined and whether they were received in a satisfactory condition.

A wealth of operating records has been accumulated in the area of sanitation. Here the basic index is the number of field visits made, usually tabulated by type of visit. Often the number of abatements accomplished is of value. Some environmental sanitation units maintain extensive statistical compilations. These are often justified because of the wide coverage of the assignments and responsibilities in sanitation.

The evaluation schedule (3) of the American Public Health Association is a notable contribution to service statistics. Although the schedule is geared primarily to measure problems and to provide an evaluation of services available in a health department, it has led many public health agencies to become conscious of the need for, and value of, regular statistical records of activities. An outgrowth of the evaluation schedule are health practice indexes which have caused many local communities to realize their inadequacies or perhaps their proficiency. There are doubtless other operating records meeting a specific need in public health. It should be pointed out that while tabulations of cases and deaths are basic to public health, they are essentially records of occurrence rather than records of activity.

Problems of Compilation

"What is a home visit?" is a seemingly simple question, but to define it so as to assure standardization is difficult.

How does one record a partly completed procedure? Or what happens when the usual effort and time were expended in an activity, but there were no results? What happens when there were multiple accomplishments on one call? The accurate defining of geographic limits in the compilation of field service must be clear and concise: They must be understood if the statistics of operations are to reflect activities accurately.

Standardization

Ideally, the recording form should be one on which data may be quickly and easily recorded by a check mark without written explanation. Coupled with this ideal factor, however, is the seemingly contradictory need for adequate spacing and for clarity.

Attempts have been made to create standard forms of operating records. While experience is valuable in the preparation of forms, and while some day, perhaps, standard forms will be developed for definite purposes, it is probably naive to expect that the compilation of operating records can be standardized because of the variations in problems and in administration. Noteworthy, however, is the success which some States are now experiencing in statewide tabulations of selected data.

The publication in 1935 of "Recording of Local Health Work" (4) pointed the way to better forms in public health. Although the forms suggested therein did not always meet a specific need, the publication of the recommendations, which were developed through the cooperation of the Committee on Administrative Practice of the American Public Health Association, did emphasize the value of a consistent system of forms. It pointed up the value to be realized from careful planning and study of forms as an initial step in any record or statistics project.

Too Much Detail

Perhaps the greatest potential problem in the compilation of operating records is the temptation to gather too much detail and thus create a burdensome procedure. Operating records must be kept to the minimum of necessary data, or a Gargantuan procedure may result. The temptation to gather data affects nearly all.

It is so easy to speculate on what would be "nice to have," and let the items build up in the tabulations. Consideration of what practical use will be made of data should be foremost in the planning of operating statistics tabulations. The research worker may gather survey data on a sampling basis, or he may gather complete data during a limited period of time. Data which are only for information or for special purposes, or which have no application to administration or to the measurement or solution of a problem, should not be allowed to creep into permanent tabulations.

Then, too, the careful administrator will make certain that a statistical report does not become an end in itself. It is always possible for work to be done just for the benefit of the reports. To be justified, statistical data must be used.

Financial Records

Aid to the administrator in management of his organization is the primary objective of compiling cost data. Their most important use, administratively, is for period-to-period comparisons of performance costs for a particular activity. When costs increase significantly over those of an earlier period, investigation is suggested. If the increase in cost is justified and no action need be taken, it is often found that the increase may be caused by some factor which can be eliminated or corrected. Cost figures, therefore, are an indication of significant changes in program.

An administrator possessing valid financial information may choose which of two worthy programs will produce the most benefit when only a limited sum of money is available. Relative costs of each of several programs, particularly when units of service may be priced, are useful in evaluating the work. Detailed program costs are of value in seeking special grants, for such requests must be predicated upon a preconceived project in which the anticipated cost must be stipulated.

Aid to more accurate budgeting is a second objective of a cost system. At best, it is difficult to estimate in advance the financial requirements of an organization. In governmental budgeting it is often necessary to estimate expenditures as far ahead as 2 years. When costs

be known and the quantity of work can be estimated, a unit cost may be applied to these estimates as a basis for arriving at the appropriations to be requested. There are limitations in the use of unit costs in budgeting, and such use may be found to represent a two-edged sword. Many activities in public health are intangible and cannot be easily measured by traditional workload statistics. Easily understood by budget officials are the elementary statistics of man-hours, units of performance, or, more specifically in city or State administration, the number of licenses issued, the number of miles of highway constructed, the number of beds maintained, or other measurable activities. But in public health administration, we must prepare budget substantiations with an intelligent use of statistics so as to reflect accomplishments and progress, or at least measure the extent of a problem.

A third objective of a cost project is to inform the public of the cost of public health. Such figures are often useful in answering questions or criticism. We are constantly faced with a need for emphasizing the economies of prevention when the costs of prevention are compared with the costs of treatment.

Two general patterns are followed in the handling of governmental financial records. In one, which is commonly termed the line item budget, specific and separate appropriation is made for each individual job or group of jobs by organization units. Operating expenses and capital outlay for such units are also separately itemized, that is, a separate appropriation is made in each program for postage, telephone, printing, travel, and for all the various classes of operating expenses. A tabulation of expenditures against a line item budget produces a cost system of direct costs. If a unit were entirely self-contained, including all administrative expenses, the process of determining the cost of the program would be greatly simplified. Such, however, is rarely true.

The other general plan of budgeting is through means of a blanket appropriation for the total operation. It may be implemented by a cost accounting system wherein each item of salary and expenditure is charged to certain programs or functions. The appropriations are justified by estimates based on previous

experience and costs. In this pattern, costs are developed on a cumulative basis month-by-month.

However, the fiscal systems of most governmental agencies are a combination of these two general patterns, in varying degrees. One complication is that many of the personnel in public health agencies are engaged in generalized programs, rather than in specialized services. Nurses, for example, are involved in many or in the entire gamut of public health activities.

Other Record Needs

A new need for cost figures in public health operation has arisen for insuring the validity of categorical grant expenditures. The Public Health Service and the Children's Bureau have found it desirable to request much more detail from States in justification of congressional appropriations. The problem arises because through generalized services, the same personnel will work in the fields represented by more than one Federal grant.

For example, it is proposed in some situations to assign a unit cost to a nursing visit, based on a time and a cost study. Others will assign a unit cost to units of service, such as an immunization, or a clinic visit. In the laboratory field, validity can be verified by using the number of examinations of various kinds multiplied by the unit cost per specimen. Such unit cost can be determined either by an analysis in the laboratory or by accepting other cost data.

The need for justification of expenditures further underlines the desirability of greater attention to costs in public health agencies generally.

Unit Costs

In determining the costs of an activity in a generalized operation, the allocation of personnel time or salaries looms as the most important single factor. The problem is essentially one of the division of an individual's time on a basis of hours spent on the particular programs, and segments of programs, which he serves.

First Opinions, Then Observations

. . . Now Measurement and Analysis

—from remarks by Dr. Haven Emerson
at the summary session of the Second
Conference on Public Health Statistics

In the beginning there were ideas and opinions, then observations, and these led to measurements, and this required numbers which led the mind of man from fingers to stellar spaces and predictions of eclipses. Facts and records, once accepted, tempted minds into their logical deductions, so arithmetic and logic grew together and have been inseparable.

Whether for war or slave labor, man was counted in early times, and distances were measured on land and sea and in the heavens. Our common interest has been in the human family and its social aggregates, their origin, growth, and decay, and the causes of these. Our first early concern was with reproduction of our kind and their survival, and only in today's times is there concern with their endurance, with quality and content of life.

As the first job of the physician was with the sick, the first concern of the health officer was with loss of life and with known preventable causes. He was a lone soul crying in a wilderness of disease. He sought to prevent, and thereby assumed society's heaviest burden. He aimed at the demos, the socius, rather than

at homo, the man. He was government's early agent of the biological sciences, the community guardian against the errors of inheritance, environment, and acquired habits of work, shelter, food, play, and reproduction.

Today he is a symbol of that composite branch of local government, the health department. He is not a person, but the personification of a group of specialist professions and technologies—physician, engineer, nurse, laboratory director, epidemiologist, statistician, educator, dentist, and veterinarian.

Permit me to recall the fact that health departments have been created to avert preventable diseases, to protect the community against factors of environment affecting health, to teach the laws of human biology so that longer, deeper, broader lives can be assured and not merely survival of the babe. Care of the sick is best done by a physician sought by the person in need of prevention, diagnosis, and treatment. The health department is a multiprofessional team, and in that team the statistician is an incorruptible bulwark against bungling in life-saving and life-giving services.

Public health personnel are highly trained professionally. They are attuned to educational and research work, but often they are unfamiliar with the record requirements of a production operation. While it is relatively simple in a manufacturing plant to determine with a stopwatch the time taken on an assembly line for each of many detailed operations,

the stopwatch application is seldom appropriate to public health time studies.

Simple time studies may often be made in laboratory or in vital statistics procedures. In laboratories, a specific time usually may be established for each operation, and the beginning and ending points of such a function are rather clearly defined. They are less clear in

the routine recording of vital statistics data where the staff member must do a certain amount of interpreting, as the recording function is only partly mechanical. Beyond this, most public health operations are not routine but require deliberation, and thus an arbitrary evaluation in terms of time is difficult.

Nevertheless, reasonably satisfactory data may be accumulated in determining the standard or average time which an activity takes. A broad base is one safeguard to assure the validity of such data. Surveys to determine the average time required in a particular type of field visit should cover a long enough period so that seasonal effects will be truly reflected, and so that the extremes will be considered.

In determining personnel costs, other factors besides direct time must be considered: the cost of vacation salaries, of overtime, of retirement, and of office time occupied in conferences, in meetings, and in report writing. A special problem in time allocation is the handling of the travel time which an individual spends in transportation as distinguished from the cost of transportation.

To conduct a continuous record of time accounting becomes burdensome and not very fruitful. Surveys, special studies, or sampling techniques are an answer to the problem of record keeping.

Operating expenses form the next general component of the financial costs of a program. Here we find the actual costs of travel and transportation, as well as costs of supplies, laundry, stationery, forms, postage, and the many other necessary continuing expenses. General overhead includes such items as office rent, utilities, telephone, furniture, professional expenses, and other related items. These costs must all be considered on an appropriate pro rata in the total program cost.

The National Organization for Public Health Nursing carried on studies of the detailed costs in public health nursing since 1922 and provided methods of cost accounting whereby a nursing service may easily determine its costs. Part of its pioneering work was the development of a time study work sheet which accounts for a nurse's time in three categories: first, the "component," which is travel, preparation, or the activity itself; second, the "cost

center," or the type of activity which was conducted—a visit, a clinic, a school, group teaching, and related functions; and third, the "service," which is the program in which the nurse is engaged, such as infant health, tuberculosis, acute communicable disease, or others. The time of the nurse is divided; each unit of time shows all three elements.

For a time study to be valid, all time of personnel must be accounted for, so that the total allocated cost will add up to the total expenditures. This often requires the recording of unproductive time, and sometimes the accounting itself serves to encourage full production. Again, it is worth emphasizing that the problems of time recording in public health are much more complex than they are in simple production activities. For example, in an automobile repair shop a mechanic will stamp the time he begins the job and the time he ends the job on each job ticket, and the customer pays for all time between such recordings. While this is the theory applied to time studies in public health, it is much more difficult to put into practice.

A good reason for determining unit costs in some situations is to provide an appropriate basis for charging or billing the recipient of the service, as illustrated in the management of a hospital, or in a visiting nurse function. This element is usually lacking in public health activities.

Detailed costs, however, are not always necessary for good administration. Costs should be determined only when they are needed. A tabulation of the number of units of performance is often the only computation justifiable as an aid to administration. Care must be taken that the cost and statistical procedures do not build up so that they occupy more time than is necessary. Cost figures are of diluted value unless they are promptly recorded and are available. Timeliness of such data is exceedingly important if they are to be properly used.

Great care must be exercised in attempting to compare costs between several agencies. Because so many variables exist, comparisons must be thoroughly explored. Travel time in urban areas differs from rural areas. Differences in salary rates, in the purchasing value of the

dollar, and in the services available and the plans of operation make large variations in program costs. The same methods must be followed between various agencies if comparisons are to be made. Comparisons of costs are often deceptive if they are lifted out of context and compared without careful analysis.

Summary

Operating statistics may be a valuable aid to determining program costs. While the gross cost of a program may be estimated from some budgetary statements, in a generalized public health operation statistics are necessary to properly segregate such costs by program.

Statistics as to service or performance units are a basic element in public health administration, having much value for administrative, budgetary, and educational purposes. In many situations, it is unnecessary to perform the additional computations to determine the financial costs.

The time which each individual service activity requires can best be determined by surveys, studies, or sampling. Continuous routine reporting of detailed time breakdown should be avoided.

There are many hazards in the statistical procedures leading to the computation of program costs, but the principal one is the temptation to allow the reporting and recording procedures themselves to become arduous and unduly complicated.

The detail of cost data to be accumulated should be dictated by the needs for it. Excess tabulation of cost data should be avoided, since for many purposes the statistical data alone may be used profitably, without the dollar figures.

Statistics and Statistical Methods in Public Health Practice

With this issue, *Public Health Reports* completes publication of 16 papers presented in June 1952 before the Second Conference on Public Health Statistics at the School of Public Health, University of Michigan. These papers, with a number of others, are to be assembled in a one-volume proceedings and will be available from the school at Ann Arbor. Listed below are the papers in the order in which they were published:

Vistas in public health statistics—by Clarence J. Velz, August 1952, pp. 725-728

Application of statistical analysis in a health program—by Ruth R. Puffer, August 1952, pp. 729-736

Current methods of collecting statistics of health and health problems—by O. K. Sagen, August 1952, pp. 737-740

Statistics in the administration of a State health department—by John D. Porterfield, August 1952, pp. 741-746

The administrative value of statistics to a local health officer—by Berwyn F. Mattison, August 1952, pp. 747-754

Needed improvements in mortality data—by Iwao M. Moriyama, September 1952, pp. 851-856

The survey approach to morbidity and health data—by Halbert L. Dunn, October 1952, pp. 998-1002

Sampling and field procedures of the Pittsburgh morbidity survey—by Daniel G. Horvitz, October 1952, pp. 1003-1012

The sampling of records—by Robert E. Patton, October 1952, pp. 1013-1019

Entomological survey methods—by Robert E. Serfling, October 1952, pp. 1020-1025

A sample survey of home injuries—by F. M. Hemphill, October 1952, pp. 1026-1034

Usefulness of communicable disease reports—by Ida L. Sherman and Alexander D. Langmuir, December 1953, pp. 1249-1257

Birth statistics in maternal and child health programs—by William Haenszel, January 1953, pp. 71-80

Statistics in a health department medical care plan—by Matthew Taback and Huntington Williams, February 1953, pp. 157-166

Public health operating statistics—by Robert G. Webster, May 1953, pp. 467-473

First, opinions, then observations . . . Now measurement and analysis—from remarks by Dr. Haven Emerson at the summary session of the Second Conference on Public Health Statistics, May 1953, p. 471

Fog and Deaths in London, December 1952

By JOHN A. SCOTT, M.D., D.P.H.

DURING the first half of December 1952, the London area experienced periods of fog, one of which was of an intensity rarely reached in recent times. This fog was widespread and persisted for a considerable continuous period, from December 5 through December 8.

Its onset was determined by the meteorological factors of almost complete absence of wind or air movement and low temperature, which produced what is technically described as an "inversion" whereby the normal upward air circulation by convection currents was arrested. Hence at ground level and for many feet above, there was no air movement, and smoke, sulfur oxides, and other air contaminants increased to concentrations much above those normal for the winter season.

Atmospheric Pollution and Temperatures

In addition to the many monthly assessments of atmospheric pollution made at several observation stations, which, of course, yield only monthly averages and hence do not show the daily variations, the chemical branch of the London County Council public health department maintains daily observations of smoke and sulfur dioxide at three places: London County Hall; Northern Outfall Works,

Beckton; and Southern Outfall Works, Crossness. The figures for the determinations at London County Hall for the period November 16 through December 27, 1952, are shown in table 1.

As a basis of comparison, it should be stated that the summer (June) daily average concentration of smoke is about 0.12 milligram per cubic meter of air; of sulfur dioxide, about 0.07 part per million. It will be seen from the table that the degree of atmospheric pollution in winter is considerably greater, as would be expected. The figures for November 1952 are generally of the order usual at that time of year, but a sharp rise in pollution occurred on December 5. Maximum averages were reached over the weekend, ending at 10 a. m., Monday, December 8; the average concentration of smoke was 4.46 milligrams per cubic meter of air, and of sulfur dioxide, 1,339 parts per million. These are exceptionally high figures, indeed the highest which have been traced in our records, those for sulfur dioxide dating back to 1932. For the 6-day period from December 5 through 10 the atmospheric condition was continuously bad, as will be seen from table 1.

The mean daily temperatures recorded at Kew Observatory for the same period, together with the departures from the average experience of the past 80 years, are shown in table 2. On December 5 there was a striking fall in the temperature, and low temperatures continued until the fog lifted.

Dr. Scott, who has served as medical officer of health in Fulham, Barnsley, and Shipley in England, became medical officer of health of the London County Council in 1952. He succeeded Sir Allan Daley, whose deputy he had been since 1945. Dr. Scott submitted the report appearing here to the council's public health committee on January 27, 1953.

Daily average concentrations of atmospheric contaminants and daily temperature departures from 80-year average, London, November 16 through December 27, 1952.

Increase in Deaths

The deaths registered weekly in the administrative county of London from November 16, 1952, to January 10, 1953, were as follows:

Week ending	Registered deaths
Nov. 22, 1952.....	753
Nov. 29, 1952.....	853
Dec. 6, 1952.....	945
Dec. 13, 1952.....	2,484
Dec. 20, 1952.....	1,523
Dec. 27, 1952.....	1,029
Jan. 3, 1953.....	1,372
Jan. 10, 1953.....	1,216

For the weeks ending November 22 and 29 and December 6, the number of registered deaths was normal for the time of year, although during the vagaries of the winter weather it is usual to find as many as 1,100 registered deaths in occasional weeks. But for the week ending on December 13 the number of registered deaths rose to a figure far above the normal winter maximum and, although somewhat less for the weeks thereafter, the number continued abnormally high. (The apparent drop for the week ending December

Fog Over London

"A report on the London fog of December 1952 has now reached the London County Council and it makes grim reading. In the past hundred years only the peak week of the influenza pandemic in November 1918 produced more deaths over the expected normal than did the man-made fog of 2 months ago. Even the cholera epidemic of 1866 could not quite equal it.

"Analysis of the deaths registered shows that extremes of life were more affected than the middle groups and that the increase in deaths was associated almost entirely with disorders of the respiratory or circulatory systems. The January 31, 1953, issue of *The Lancet* contains an interesting account by a general practitioner of the effects of the fog on his Beekenhams practice. Upper respiratory toxic irritation appears to have been common and affected the active as well as the older and less fit whilst lower respiratory affection occurred amongst the more elderly and those with a previous

history of chronic chest trouble. Dr. Fry notes that the majority of these illnesses started fairly abruptly on the third or fourth day of the fog.

"This combined picture of mortality and morbidity is similar to that presenting itself at Donora and in the Meuse Valley. It is the picture presented by the London fog of 1948 and it is a reiteration of what the medical officers of health of Glasgow, Leeds, Manchester, and other industrial cities have been reporting in greater or lesser degree from time to time for several generations. In other words, the London fog of December 1952 was no strange new phenomenon. It was no acute epidemic caused by a hitherto unrecognised virus nor was it a visitation of some known pathogen against which we had no defence. It was simply the occurrence of a well-known meteorological phenomenon in an area where the toxic products of combustion are vomited in excess into the air and as a result the upper and lower respiratory

systems of the local inhabitants were irritated and death occurred amongst those with pre-existing cardiovascular and respiratory disease.

"This is in parallel with typhoid at Croydon and Malden and paratyphoid at Bournemouth and Aberystwyth. What does it matter if in the one the vehicle was air and in the others water, milk, and ice cream? The result was the same. Epidemic illness of a preventable nature occurred. . . ."

—Excerpt from an editorial appearing in *The Medical Officer*, London, February 14, 1953, p. 73.

Other London fog reports appearing recently in *The Lancet*, include: "December Fog in London and the Emergency Bed Service," by G. F. Abercrombie, January 31, 1953, pp. 234-235; "Effects of a Severe Fog on a General Practice," by J. Fry, January 31, 1953, pp. 235-236; "Mortality in the London Fog Incident, 1952," by W. P. D. Logan, February 14, 1953, pp. 336-338.

27 is due to the usual delay in registration over Christmas and not to a decline in deaths.)

The general death rate for the week following this fog and cold was slightly greater than that associated with the severe fog of 1873 and was comparable with the rates experienced at the peak mortality of major epidemics, as shown in table 3.

It is apparent that although the death rates immediately following the fogs of 1873 and 1952 were almost the same, the increase was much greater in 1952. The increase in 1952 was larger even than that attributable to cholera in the

week of highest mortality in the summer of 1866.

Deaths by Age and Cause

Analysis of the deaths registered weekly from November 16 through December 27, 1952, shown in table 4, indicates that the sudden increase in mortality, although more pronounced among infants and the elderly, was not confined to persons of any particular age. Among infants aged 4 through 52 weeks and among persons over 55 years, three times as many deaths were

Table 3. Registered deaths per million inhabitants in the administrative county of London during specified weeks

Week ending	Deaths	Normal for period and season	Excess over normal
Aug. 4, 1866 (cholera).....	876	450	426
Dec. 20, 1873 (fog).....	713	470	243
Nov. 9, 1918 (influenza).....	1,085	300	785
Dec. 13, 1952 (fog).....	745	300	445

registered in the week ending December 13 as could be expected from the figures for the previous 3 weeks, and among persons of all other ages, rather over twice as many.

The causes associated with the excess deaths were confined almost entirely to disorders of the circulatory or respiratory systems (see table 5). Compared with the average per week for the previous 3 weeks, deaths from bronchitis in the week ending December 13 were 10 times as many; from pulmonary tuberculosis, $4\frac{1}{2}$ times as many; and from other respiratory diseases, nearly 6 times as many. Deaths from cancer of the lung rose rather less, to nearly twice as many; those from disorders of the heart and circulatory system were nearly three times as many. Deaths from any other defined

cause showed no significant increase with the exception of gastroenteritis, deaths from which increased considerably among children under 1 year old; it is, however, quite possible that these cases of gastroenteritis were secondary to an upper respiratory infection.

This sudden high mortality did not alter the normal pattern of deaths from the different causes at different ages except insofar as it was an increase confined to respiratory and circulatory diseases; at no age were any excess deaths registered from causes which are not normally characteristic of that age during winter. Deaths from influenza, although they rose markedly in the week after the fog, rapidly fell back to a normal winter level and at their highest were well below the numbers to be expected in a developing epidemic.

Detailed comparison of the deaths following the fogs of 1952 and 1873 is not possible owing to considerable changes in the methods of classifying causes of death. But it is clear that the effects were broadly similar. In 1873 as in 1952, it was the respiratory and circulatory diseases which showed the greatest jumps in mortality; and in 1873, although the death rates increased at all ages, the increase was much greater among the very young and the old. An accurate comparison between the se-

verity of the 1873 and 1952 fogs cannot be made since no recordings of the condition of the atmosphere are available for 1873. But some idea of their relative intensities can be obtained since it so happens that in both years the fog occurred while the Smithfield show was being held, and in both years deaths of animals in the show were recorded. The *London Times* of December 12, 1873, reported that about a third of the animals had to be removed; that some were saved by being carried quickly into the clearer air of the country but a considerable number had to be slaughtered; and that asphyxiation of animals occurred in London cow-houses and in the metropolitan market on De-

cember 11. In 1952, the breathing difficulties experienced by otherwise healthy animals owing to the foggy atmosphere received wide publicity.

Summary

During the week following the fog and very low temperatures of December 5, 6, 7, and 8, 1952, abnormally large numbers of persons at all ages died from causes connected with difficulty of breathing. This was very similar to what had happened immediately after a comparable fog in 1873, but the rise in deaths in 1952 was much greater and was, in fact, as great as that during the worst week of the last cholera epidemic.

"Widening the Road to Health" was the theme of the eighth National Conference on Rural Health sponsored by the Council on Rural Health of the American Medical Association. More than 700 medical, farm, and community leaders, representing several million rural area people, attended the conference at Roanoke, Va., February 27 and 28. Our report of the meeting begins with a review of conference activities since 1946 by Dr. Crockett, chairman of the Council on Rural Health. It includes in news-summary form reports of seven other papers and, in brief, a review of rural dental problems. Two additional briefs summarize the viewpoints on rural health councils of a physician and of a State public health director. These were given at a preconference meeting of State committees on rural health. The seventh National Conference on Rural Health was reported in Public Health Reports, May 1952, pp. 479-483.

Looking Back To Look Ahead in Rural Health

By F. S. CROCKETT, M.D.

A REVIEW of the past 8 years may help us in forecasting where we go from here. Let us, in part, recreate the atmosphere in which we lived in 1945. A great world war was ending. Nearly all civilian activities had suffered change and dislocation. This was especially true in health and medical care. Some 60,000 physicians had entered the armed services, in many instances leaving communities without a physician or with an aging one.

Earlier, in the midthirties before World War II, the decreasing number of physicians in the small towns was impressive. This phenomenon had been slowly developing since the beginning of the century. The element of need seemed increasingly urgent. The big question was what could be done about it?

Dr. Crockett, Lafayette, Ind., is chairman of the American Medical Association's Council on Rural Health.

The American Medical Association formed a committee on rural health, predecessor of the present council, in response to an invitation from the American Farm Bureau Federation, an organization representing at that time about 1 million families from farms in practically every State. Individual physicians were fully aware of the rural health situation and were anxious to make available all the resources and information in their possession required for study and solution of the problems.

In the organizational plan for the medical profession eight areas of rural America having comparable rural health problems were recognized. A member of the committee living in each area was given responsibility for developing rural health activity suitable and acceptable to the people in the area. This intimate knowledge of sectional problems was augmented by advisory members. We first invited advisory members from the Farm Bureau, Grange, Co-operative Milk Producers Federation, Farmer's

Union, and Farm Foundation of Chicago. Later the Committee on Policy and Planning of the Land-Grant Colleges and the American Agricultural Editors Association gave us advisory members. We have received recognition and support from constituent State medical societies. Forty-three State rural health committees have stimulated interest in providing service for their rural areas. They have done much to organize State and local health councils, enlisting the support of a large segment of the citizens. The State committees have received major support from many sources, especially farm organizations, which have also organized State and local health committees.

Ground Rules

Into conferences such as this one flow the combined thinking and planning of the rural and professional leadership of the whole country. This combination of skill and experience justifies our claim that rural health promotion has become truly a citizenship responsibility—a duty resting upon each citizen to contribute, to the fullest extent of his knowledge and experience, the wisdom required to make any community effort succeed.

The first national rural health conference, held in Chicago in March 1946, had several unique features. For instance, it was not a meeting of physicians to solve a health problem. It was a meeting of physicians and laymen to discuss and solve their mutual health problems—tacit recognition that rural health is a job for the citizen and that it requires community cooperation. The conference was national in scope—some 3,500 invitations were extended to all groups thought interested in the problem. Nearly every State was represented.

The ground rules for the conference called for an open forum in which everyone was free to express his opinions. It was believed that through a multitude of ideas a more complete picture would evolve. The conference was exploratory with no preconceived ideas to be supported. Discussion from the floor was deemed

important, equal to the prepared addresses.

The American Medical Association, while sponsoring the conference, claimed no privileged position. Constructive criticism was expected and desired. There were to be no decisions by majority vote. Truth cannot be established that way. Instead, areas of agreement were sought. Disputed problems have often found solution with the passage of time and more experience. These ground rules have not been changed. They apply with equal force to this eighth conference.

Three statements epitomize some of the thinking at the first conference.

The late Ransom Aldrich of Mississippi, first chairman of the Rural Health Committee of the Farm Bureau, pointed out, "The chief problem of medical care in rural America is cost. In my county, doctors charge a dollar per mile. The low income group in rural America simply does not get medical service from that kind of charge."

Dr. L. W. Larson, North Dakota, a member of our committee, remarked, "Rural health has always been a problem. While there has been considerable improvement, two phases remain unsolved—the availability and the cost of medical care. (a) Availability means bringing the doctor to the patient or the patient to the doctor. (b) The cost will be less if the patient can go to the doctor. The use of prepayment plans will spread the cost and reduce the cost to the individual."

Leland B. Tate, of the Farm Foundation, proposed that better medical care and health service, and health education should bring to the individual: (a) "Knowledge and understanding of what is desirable for maximum health, and (b) insight into ways and means of getting and paying for adequate health and medical services."

Three basic factors, that still concern us, were noted and emphasized at the first conference: medical services; the maintenance of health through education of the individual; and the economic situation that exists at the moment affecting various segments of rural people.

The Common Effort

These are, in part, the progressive steps by which we have built the National Council on Rural Health and mobilized existing related professional, educational, and civilian groups for a common effort on the national, State, and local levels. What then is this common effort?

Our objective in this common effort has been the benefit of the individual and his community. The technique to be employed was, we believed, important—as important as is the objective. This benefit was not to be had free, but was to be earned by the community and by the individual. By this technique, based on rugged individualism, on personal pride in one's ability to care for himself, on meeting common problems through group action, the objective was to be won.

This basic philosophy and the methods employed in its achievement reflect the thinking of the medical profession. I believe it is acceptable to our advisory groups. We have given much thought to this whole matter. Where does the local physician, of the county medical society, fit in? True, they are the experts in health matters, but no community problem can be solved by a minor segment of the population.

We have come to believe that this is not the physician's job; it is not a job for the medical profession; it is not a public health service job; it is not a layman's job. It is a job involving all citizens collectively and equally—one in which each contributes for the common good his knowledge and experience and in return shares in a better place in which to live and rear his family.

We believe we should take advantage of the strength accruing from group action. Citizens organizations lend themselves well to health promotion, and many have been formed on the county basis in many States.

The trading center, and its surrounding trade area, is the logical health council area. It has been observed that people get medical services where they go for other commodities and services. Since the county is a convenient area surrounding the trade center, or county seat, we have come to call these local organizations county health councils.

County health councils are truly local. This is the area where people live. This is where they can conduct their local and community affairs to suit themselves. This is the level where local self-determination permits the fullest expression of individual thinking. Schools, churches, highways, public health services, law enforcement—everything entering intimately into daily living—reflect the individual's attitude toward, and concept of, his responsibilities as a citizen.

A county health council should be organized whenever a large majority of the local leaders and local citizens are ready for it. In Indiana, for example, 34 counties out of a total of 92 have health councils. Some have been very active; others shade down through varying degrees of activity. What we need in Indiana is an overall State organization interested in stimulating well-directed activities originating locally in response to local needs. A number of States have such State health councils. They have followed no set pattern, but each has contributed richly to the fund of general experience.

Any organization able to accomplish what the people want done is a good and sufficient organization. It is a well-recognized principle, however, that the best public opinion exists where the greatest number think as we do. Any organizational plan that secures a favorable public opinion and wide popular support is to be preferred. This is the way our common effort can be, and has been, implemented. This is the highway we wish to broaden now.

Steps on the Road

A brief review of the succeeding national conferences will complete the picture of our progress.

The second conference studied methods of bringing and holding doctors in rural areas; building hospitals and diagnostic facilities; medical care for low income families; and prepayment plans for medical and hospital care.

The third conference considered the health problems of rural youth. We learned that the country was no better and no worse than the

city. Each to be a healthful place to live must utilize well-known health measures.

The fourth conference studied the rural and farm environment; the accident rate; animal diseases affecting man; soil depletion effects on nutritive crops; and use of newer chemicals in pestilence control and possible poisonous effects.

The fifth conference was the first to be highlighted with a theme. A courageous "Let's Do Something About It" dominated the program thinking in 1950. It was pointed out that the community health council, if properly organized with broad interests, wide support, and wise leadership, will supply the channel through which any community can solve its own health problems in its own way and to its own satisfaction.

"Why Wait—Let's Do It Ourselves" was the sixth conference theme calling us to further action. Success stories of State and county health council accomplishments cited examples of vision, leadership, and energy exhibited under the stimulus of good neighbor and good citizenship practices. It was a dramatic confirmation of previous years' studies and recommendations.

The theme at last year's seventh conference of "Help Yourself to Health" was an action slogan in the best rural tradition. Discussions of successful planning in a number of States, and recitals of "take home" ideas garnered from the program, afforded ample opportunity for thorough discussion from the floor.

Accomplishments

The national conferences have created a receptive climate for a number of developments. Several come readily to mind such as Blue Cross and Blue Shield and Farm Bureau and Grange sickness insurance; Hill-Burton aid to hospital construction; placement service for physicians in communities wanting physicians; nurse recruitment plans; organization of State and county health councils, and organization of rural health committees by State and county medical societies.

Health educators have been added to facul-

ties of several land-grant colleges. At least two States have emphasized general practice training of medical students. Some State plans include graduate instruction which will bring the medical school to many rural physicians who cannot leave their patients without medical care while taking refresher courses.

Surveys of local health conditions by lay personnel in local health councils, under professional guidance, is a most revealing activity. We have survey reports from Columbiana County and Clinton County, Ohio; Parke County, Ind.; and Madison County, Idaho. No doubt there are other reports that have not reached us.

The compilation of much pertinent material by the Council on Rural Health, available on request to the council's secretary, should prove helpful to anyone developing a home program.

Another accomplishment of the council which has done much to strengthen and give common direction to many agencies interested in promotion of better health for rural America has been the addition of a field director to the staff. Members of the council are all working physicians who take time off from earning a living whenever they do anything to promote this cause. This limiting factor has been removed by having a full-time representative whose duty it is to go into every State and acquaint all interested persons and groups with the council and with each other. In obtaining a field director, or roving ambassador, the council's effectiveness has been enhanced manyfold. We like to refer to him as our catalytic agent, so many desirable reactions result when he is around that somehow never happened before.

A unity of purpose and performance by all of us engaged in stimulating rural people to attain a fuller and more healthful life is created by our knowing each other better and working together. This is one of our objectives.

In charting the direction we have traveled these last 8 years, we have been guided by a realization that we live in a real world; that each of us must live and act as a responsible person; that the world does not owe us anything except opportunity—opportunity to solve

our own problems in our own way and to our own satisfaction.

The Future Problem

Final solution of the three basic factors of medical care, health maintenance, and purchasing power uncovered at the first conference is our future problem.

Medical Care

Medical care is that service we require when we are sick. This we can not give to ourselves. We need well-trained doctors and nurses and well-equipped hospitals. Since 1946 this situation has improved. Many doctors have settled in the small towns. I doubt if there are now many prosperous communities, where desirable living conditions exist, without needed medical personnel. It is in communities in the lower income level that the greatest challenge exists—places where poor schools, churches, roads, homes, and farms go hand in hand with inadequate medical care.

Health Maintenance

Health is more than freedom from disease. It should have a positive quality, abundant and vital in character. We should think of health maintenance as consisting of all those things we learn to do for ourselves so that we can keep the good health we now have. This is our own responsibility. We owe it to ourselves. It is no other person's duty to maintain our health for us unless we become dangerous to the health of other people. The individual is capable of doing many things needed to maintain his health. Of course, there are some health problems that require community action. The local public health service was created for this purpose and needs and deserves the support of all citizens. It is an official body created and governed by law. A volunteer organization is more resilient. It can make and change its own rules to meet quickly any emergency. There is much that such a citizen's council can do to make everyone health conscious. This is not a new or untried idea. In many counties in a number of States such groups have done excellent jobs

in cleaning up health hazards and teaching the simple rules of health.

Purchasing Power

The third basic factor involves purchasing power—the “take home pay” in rural areas. Price parity is equality of earning opportunity. Its realization would go far to solve the medical care problem and payment for the service. There are today few prosperous rural communities without needed medical coverage. However, they too will benefit from local organization. There is more to this problem than getting a physician and paying him for his skill. Public opinion can be mobilized in support of many improvements in hygiene, sanitation, and other health measures.

Sharing and spreading the costs of medical care through insurance is of interest to everyone, rich or poor. In the purchase of goods and services, a sliding price scale cannot be applied as it is in taxation. Great progress continues in the insurance coverage of rural people and we can entertain a reasonable hope of the eventual coverage of 60 percent or more of those who should have it. The greatest challenge is how to bring the benefits of prepayment to the 40 percent.

To these problems, there is no easy, simple answer. All the points I have made are debatable. There is an honest difference of opinion. But there is much evidence warranting the conclusion that the future trend is away from “statism”, with a return to individual initiative, to voluntary organization on the local, State, and national level for the meeting of social needs. The promotion of local organization for this purpose by the past seven conferences seems timely and even prophetic as we view it now.

We must continue to encourage county or community organization. Continuing education is the best method for achieving our goal of individual and local self-help. It is the sure foundation for State and national solution of health and other social problems. There is no substitute for a well-informed citizenry.

In taking a long look ahead, physicians will do well to follow Dr. Louis H. Baner, president

of the American Medical Association. Recently he urged the expansion of voluntary health insurance to cover the aged (those over 65 years of age) and those suffering from illness of long duration; promotion of volunteer organizations so that we can have a better distribution of physicians through establishing needed facilities; making good medical care for the indigent available everywhere; extension of public health coverage to areas lacking it; and protection of the public so that people may always obtain the services of a physician.

During the past 8 years we have been making progress in line with these suggestions and the potentials are much greater than anything that has been accomplished up to now. We are given an unprecedented opportunity for service to society. Our goal is the well-served, well-informed community. We must reach our goal by showing that the way along the ever widening highway to health is gained by patient and sturdy trudging. It is not a journey that can be made by thumbing our way.

Highlights of the Conference

Group Health Insurance Advised for Farm Families

Group health and accident insurance gives farm families an economical way of meeting medical care costs, Carl S. Mundy, M.D., Toledo, Ohio, vice chairman of the Council on Rural Health told the Eighth National Conference on Rural Health.

Dr. Mundy pointed out that group coverage with payroll deductions is the most economical form of insurance. This method, he said, has been adopted by many industrial and business concerns.

"Since payroll deduction is impossible for farm families, some other satisfactory and economical arrangement must be made to collect and forward premiums for the group," he added.

Farm organizations and church groups have served this purpose, he said. "Enrolling all the depositors in a rural bank and authorizing the bank to deduct premiums from the contract holder's account and to forward them to the insurance company is another method that is working well in many communities. The prime requisite in each instance seems to have been imagination and leadership."

Dr. Mundy stated a group must be not only qualitatively representative, but quantitatively it should in-

clude more than 50 percent of the farm families in a community or locality.

He also pointed out that the farmer would have a more economical and better coverage for his purpose if he took advantage of the deductible principle which eliminates the insurance of small, frequently recurring and unpredictable items.

"The greater the number of small items we permit to remain in this deductible category, the cheaper will be the insurance," he said.

According to Dr. Mundy, the hospital bill probably will be the largest item in the cost of a major illness. Surgical fees are usually the second largest item when surgery is performed.

"There are many sources of insurance available," he said. "Commercial carriers operate in most States. In many States there are companies sponsored by the Farm Bureau, the Grange, or both. These, together with Blue Cross and Blue Shield, offer a variety of contracts that should satisfy the needs of most groups."

Facts on Food Values Needed in Rural Areas

Farmers need to know more about food values, Janet L. Cameron, Blacksburg, Va., food and nutrition

specialist for the Virginia Polytechnic Institute's agricultural extension service, told the conference.

Miss Cameron reported that a survey in Appomattox County, Va., a fairly typical rural area, showed that three groups of foods were seriously lacking in the diets of more than half of the families. These are tomatoes, citrus fruits, and other vitamin C foods; milk and milk products; and green and yellow vegetables.

"Even though farm families usually produce much of their vegetables and part of their fruit and meat, the largest part of their income goes for food," Miss Cameron said. "Therefore, a big responsibility in nutrition is to help them understand food values in order to get the most for their dollars."

"It may help our people to know that green cabbage is now much cheaper than lettuce, yet just as nutritious; that pork liver is far more nutritious than sausage or ham, yet the cost is much less. By the same token, beef liver or heart has more iron and vitamins than beef steak or roast, yet it costs far less. If the cost of fresh milk limits the amount a family can use, canned or dry milk is equally nutritious."

"Lack of income may limit or prevent some families from getting an adequate diet, but most farm families can have a garden and produce enough vegetables to give them two

... of food which studies show they lack."

Focus on Youth

Miss Cameron said progress in nutrition since World War I has prevented or alleviated dietary deficiency diseases, such as: curvy, rickets, and simple goiter. Synthetic nutrients have made it practical to improve common foods as a means of preventing deficiency diseases in large populations, she added.

Studies show that the poorest fed member of the family is the adolescent, especially the girl, Miss Cameron pointed out, adding: "Somewhere along the line we have failed to establish in her the good eating habits of her childhood, or we have not helped her to see the importance of nutritious foods for her happiness and success in the years ahead."

New Hospital Achieved By Community Action

The record of a small town—with a population of less than 5,000 people—successfully passing three bond issues to build a 55-bed hospital was reported by Lilyan C. Zindell, Perryville, Mo., administrator of the Perry County Memorial Hospital.

Everyone seemed to want to participate in the project, Miss Zindell said. The Missouri Farm Bureau Federation gave a helping hand. Former residents of Perry County living in St. Louis also contributed.

The hospital has attracted four young physicians into the community. In less than 2 years, 800 babies have been delivered without a maternal death. Local businessmen and farmers serve on the board of trustees, she said.

Hospital Volunteers

Since the hospital was opened a group known as the "hospital volunteers" have sewed several thousand items needed by the hospital and have served as receptionists. Currently, they are working to create a student loan fund for use by young people in the community who go into

schools representing the professions that, combined, make the hospital team.

Miss Zindell urged other communities to consider the financing of the medical education of qualified local youths as a means of assuring a supply of doctors for their areas.

Community Shows Way To Get Physician

Huddleston is a Blue Ridge mountain town in Bedford County, Va. Its population of about 250 is hardly enough to cause a physician to give it consideration as a place to practice.

But the people of Huddleston were of the opinion that they needed a physician, and they were determined to get one. Six months ago, they did. Now, they have a clinic which they helped erect and where a young physician serves from 250 to 300 patients a week. These patients come from a widespread area.

The story of community enterprise which changed the medical care picture of the small town and its surrounding country was told by Earl J. Shiflet, Richmond, Va., State deputy of the Virginia State Grange.

The story is this:

In the spring of 1951, the newly organized Otter Grange of Bedford County included in its community program plans for obtaining a physician.

Organizational Help

A request was made of the Bedford County Medical Society to ascertain whether there was need for a physician in Huddleston. Within 10 days, the society reported there was a need and expressed the opinion that a physician could develop a good practice.

The Virginia Council on Health and Medical Care gave the community a list of physicians seeking a place to practice, and Huddleston was placed on the council's list as desiring a physician. Among those

contacted was a 29-year-old 1951 graduate of the Medical College of Virginia, who interned in the Norfolk General Hospital, and was seeking his first location.

The Otter Grange, in its planning, was joined by the Parent-Teacher Association and by other groups in the community. The young physician visited Huddleston and showed an interest. The community offered to make certain provisions in order that he might be able to start his practice without too great a financial burden upon himself.

Build Clinic

A trust company was formed to represent the community in an agreement with the physician. It was decided that the physician should have a clinic in which to practice and a desirable place in which to live. The physician was consulted on the type of clinic, and it was agreed to build a cinder block building consisting of a reception room, an X-ray room, doctor's office, examining room, and a laboratory. It was to be rent free the first year, after which \$500 a year was to be paid. The physician was to receive first option on the purchase of the clinic within 10 years.

An old, used school building near the clinic was converted into a comfortable and attractive residence for the doctor and his family at a \$70 monthly rental.

Mr. Shiflet paid tribute to the physician, saying:

"This was his first practice. He was setting up practice in a strange community. He was strictly on his own in a new kind of medical experience, with no one to fall back upon for advice. He had a family to provide for.

"First, and most important, he started off by giving good medical service to his patients. Residents of the community will testify to this.

"He has followed a strenuous schedule, sparing nothing to meet the medical needs of his people. He has purchased good equipment to in-

sure good medical attention. He has endeavored to make the clinic comfortable and attractive.

"Patients coming to the clinic are received by a charming receptionist. To complete the staff, the doctor has employed a trained nurse to work with those receiving medical attention. To make everything as convenient for the patient as possible, an X-ray machine has been installed and drugs are available at the clinic."

Small Town Practice Chosen Over Big City

Seven years ago, a 32-year-old physician in the Army Medical Corps figuratively tossed a coin. Should he, after being discharged from service, enter into general practice in a small town in the Ozark Mountains, or should he undertake further study to become a psychiatrist in a big city?

The Ozarks won. Today, Mountain Home, Ark., has a family physician who is happy in his surroundings although the road traveled was a rough one. This story was told by B. N. Saltzman, M. D., of Mountain Home, Ark.

A 1940 graduate of the University of Oregon Medical School, Portland, Dr. Saltzman, like many other young physicians, entered the Army after his internship. By 1946, he had accumulated sufficient discharge points to consider leaving the armed services. He was stationed in the Canal Zone at the time.

He heard that the town of Mountain Home, with a population of about 2,000 and located in the north central part of Arkansas, needed a physician and that the residents were willing to go to great lengths to make things suitable for a good medical practice.

Facilities Offered

There was no hospital, but he was informed that a modern office would be provided and equipped. A home would be made available to him

and his family, and there would be a new car.

"I would, of course, have to pay for these things later, but all I had to do now was to start practicing," Dr. Saltzman said.

He went to Mountain Home, where he found there was no modern office available and no equipment; there was no home available in the town, and his query as to a new car was met with expressions of "great glee and wonderment."

But another physician in the town, who was retiring because of ill health, turned his small office over to Dr. Saltzman and acted as his sponsor. Dr. Saltzman's savings went for the purchase of a small house still under construction; his old car had to do for another year. Sleeping quarters were established in the back of the office. After 4 months, he was reunited with his family.

There was no lack of patients, however, Dr. Saltzman said. The difficulty was in finding time to care for them. "My obstetrical practice flourished, and soon I was delivering as many as four babies a day in the homes."

Home vs. Office

Dr. Saltzman stated that he had to overcome the prevailing idea that the doctor should come to the home rather than that the patient should come to the doctor's office. Eighty percent of the house calls were useless and costly to the patient because of time and distances involved, he added. After modernizing his office and installing a laboratory, he began to educate his patients to come to him. Soon thereafter, Dr. Saltzman stated, his practice grew so rapidly that help was needed. He acquired an associate.

Then, the need for a hospital became more and more apparent. However, the building of it was left to the doctor. A hospital was completed 3½ years ago. It has 12 small private rooms for patients. Home deliveries are now a thing of the past; house calls have been cut to a minimum. Dr. Saltzman and his

associates are seeing more people than formerly, although their work has been cut in half.

The University of Arkansas Medical School has selected him as a preceptor—a teacher of young physicians who are given first hand experience in the problems and rewards of general practice in rural communities.

Dr. Saltzman gave suggestions for communities which are in need of a doctor: let the doctor be invited by organized action of community leaders willing to back up their promises—don't needlessly work the doctor to death; he's human; provide a small community-owned hospital, open to all reputable physicians in the area.

Helicopter Suggested To Transport Patients

The helicopter as a possible means of transporting patients from sparsely settled rural regions to hospitals where every facility is available was suggested by Louis H. Bauer, M. D., Hempstead, N. Y., president of the American Medical Association.

"In Korea," Dr. Bauer said, "patients are transferred by helicopters from the front lines in a very short time to hospitals where every facility is available. This is something to be considered by certain rural areas."

Dr. Bauer said that the Council on Rural Health is filling a long-felt want in acting as a liaison with other organizations to improve rural health conditions.

"Now all groups are cooperating in an effort to bring the highest standards of medical care to these areas," he said. "No one organization can do the job by itself. It requires a community effort."

Attracting Physicians

"One of the difficulties in the past has been the developing of some means to attract physicians to those regions lacking them. A physician

who spent 8 to 13 years of his life in being trained to practice modern medicine is not willing to settle in an area where there are no facilities for practicing such a type of medicine. Increasing the number of physicians will not do it, as they would still tend to congregate in cities.

"In some States, the problem has been solved by the community providing medical facilities and then permitting the physician to rent those facilities or to buy them through gradual amortization. Where this has been done, physicians have been obtained."

He also pointed out that in these days of good roads and automobiles a physician can cover a wider territory than before and is able to take care of more people.

"Every community does not need a hospital so long as one is available within a reasonable distance and good roads lead to it," he added.

More GP's Needed

Dr. Bauer expressed the opinion that medical schools should train more general practitioners, and that general practice should be a prerequisite for specialization. The AMA House of Delegates, he said, has directed that a committee be appointed to study this matter.

"Our voluntary insurance plans must be made available to rural people," Dr. Bauer stated. "Public health facilities must be extended to cover all areas so that there will be universal protection against communicable disease; protection of food, milk, and water supplies; elimination of disease-bearing insects, and adequate environmental sanitation."

Auxiliary Interested

Mrs. Ralph Easden, Long Beach, Calif., president of the Women's Auxiliary to the American Medical Association, reported that the auxiliary membership, composed of 60,000

physician's wives, is actively engaged in the promotion of rural, industrial, and school health; prepayment medical care plans; health education; civil defense; and promoting good legislation.

Joint Action Cited

At a meeting of State medical committees on rural health held on the day preceding the annual conference, Walter B. Martin, M.D., Norfolk, Va., a member of the American Medical Association's board of trustees, said that the cooperation being shown by physicians and representatives of the people they serve is a splendid example of how a democratic people accomplish their objectives. "The problems of rural health are being worked out not by compelling laws, but by joint action of physicians, the public health services, and the people of the community," Dr. Martin stated.

Medical Care Insurance Seen as a Responsibility

Medical care insurance is missing from many family budgets because some individuals fail to assume full responsibility for their own family health and welfare, declared Frank W. Peck, Chicago, managing director of the Farm Foundation.

A person who neglects to plan his affairs to meet unforeseen contingencies has himself alone to blame, according to Mr. Peck.

He excepted the indigent, the aged, and persons otherwise unable to provide for themselves. Government has a role in helping these people, he said. However, he added, there has developed a growing opinion during the last quarter of a century that "preparing for the proverbial rainy day is old fashioned."

Medical care provisions are missing from many budgets, Mr. Peck pointed out, because a family may have had little experience with seri-

ous illness; their income is already being "stretched to the limit," because, in some instances, of the lack of understanding between "needs" and "wants," or they may have a tendency to "cross the bridge when they come to it."

He placed farm families with respect to attitudes toward budgets into four groups: those who budget and who may or may not include expenses for medical and dental care; those who dislike budgets because they find difficulty in keeping within them, or because of the self-discipline involved; those who are "getting along all right" and are willing to let "well enough alone"; and those who believe they will be taken care of, and look to the community or government to do it.

Education Needed

Mr. Peck offered "education" as the solution, stating: "This education includes appeal to logic and reason. It represents the teaching of values and benefits. It represents facing the economic facts of life, particularly in a business that has extraordinary risks and uncertainties. It belongs in the extension system of adult education."

Reporting on the activities of his organization, he said: "The Farm Foundation directs its educational effort to a better understanding of all plans and processes. It holds that only as rural people and medical men study and plan together will rural health programs be developed which will result in rural people raising their health standards while preserving those freedoms that are cherished by both farmers and medical men."

"In a situation so complex, difficult and dynamic as that of rural health in the United States, satisfactory solutions to all the problems involved are not to be found quickly. These problems have been developing for generations. Their solutions will require time, thought, effort, skill, cooperation, understanding, good will and patience."

County Health Councils And Public Health

P.H.R. Recognition of the essential dignity of each individual has been my guiding principle both in the private practice of medicine, in which for years I earned my living, and in public health practice, my present activity.

I should think that this basic principle would dictate the decisions of other private or public health practitioners. In fact the more difficult the decision the more we ponder about what will best befit the dignity of the individual. This is a theme worth keeping as we go forward in bringing better health to this Nation.

Without question the interest of rural groups will help bring better health not only through securing physicians for rural areas, but also through greater emphasis on preventive medicine and public health. It is also true that the presence of a local health department helps attract private physicians to rural areas. They realize that private practice has lost nothing and gained much through sound local health department services.

Physicians have limits of physical endurance. They do their best work only after families are well informed and when the families carry out their obligations by maintaining personal hygiene, environmental sanitation, proper nutrition, immunization, and by consulting the physician early rather than after complications have arisen.

Traditional functions of a local health department are vital statistics, control and prevention of communicable diseases, environmental sanitation, laboratory services, protection of maternal and child health, and health education. Another field now coming into the scope of public health was described by Dr. Thomas P. Murdock, AMA trustee from Con-

necticut, in an address to the Association of State and Territorial Health Officers last December. He said, "The field now covers many of the long duration illnesses such as rheumatic fever, chronic arthritis, cancer, crippled children, syphilis, care of the blind, and diabetes."

The Common Meeting Ground

Daily, in outpatient departments and wards of hospitals, physicians see patients in whom the neglect of health has produced minor problems of disease and patients in whom the neglect of disease has produced major problems of illness. By taking an interest in these minor illnesses at a time when the patient is ready to listen to advice, the physician has a golden opportunity for the practice of preventive medicine. We, in public health, probably need to close the gap between the level of health education and recent improvements in the training and tools with which physicians work. Patient education is an important part of public health education because sick persons are concerned primarily about their own health, and to be concerned is the first step in learning. Patients want to know what happened to them, why it occurred, and to what extent they are responsible for their illness. The best education is still transmitted from one person to another in a heart-to-heart talk.

The health council actually is a projection of the concept of preventive medicine from the State level down to the community. That is where the laity, physicians, and the public health team find a common meeting ground to begin the solution of their community health problems. These problems change with time. We all know that a different pattern exists now from the one of the early-day health officer, who was thought to be mostly occupied with tacking up varicolored signs appropriate for each communicable disease.

The Community Health Council can approach disease prevention through fact finding and interpretation of needs, resources, and problems. It can formulate standards and promote their acceptance. The council can mobilize the forces and interests in the community for sup-

By Franklin D. Yoder, M.D., M.P.H., director of the Wyoming State Department of Public Health, Cheyenne.

port, extension, and improvement of necessary services and facilities. It can help integrate related services, eliminate duplication of services and those for which there is no longer a need, and modify established services in keeping with new knowledge and changing community needs. Through central planning, informational, and referral service, the council can help promote full coordination and cooperation.

The importance of the participation of practicing physicians in community health council work cannot be overemphasized. Participation keeps physicians in touch with community health problems and enables them to give intelligent guidance to their solution.

In Wyoming we find several factors which produce interest in organizing a health council. In communities that want a public health nurse, a health council can help explain the benefits of this type of service to the people. Other communities may want to obtain a physician, they may want to take community action in eliminating a stream pollution or air pollution nuisance, or they may find it advisable to work toward building a hospital through the Hill-Burton program. Community health councils have been effective in these projects. Other conditions may help crystallize a health council in the communities of other States.

Put Into Practice.

Health education is one of our broadest and brightest avenues to better health. An illustration of how health knowledge was put into practice by a western Nebraska family was given at last year's rural health conference.

The mother had suffered a broken arm, and the children, ages 6 to 14, had taken over. They planned the meals, taking into consideration the basic food elements and good sanitation. They policed the medicine cabinet for dangerous medicine, and they were justly proud of their new plumbing system and the disposal unit, safely located. Flies were under control and rodent control was so well in hand that even the cat couldn't find a mouse. The cows had been tuberculin tested (brucellosis wasn't mentioned), and the children were figuring how to

pasteurize the milk. They had studied the soil in relation to the trace minerals and the other elements and to human nutrition. The family had health insurance and were helping with the preparation of an office building for a physician who was coming to their community.

In health education, as in other respects, the community health council can help in the development of good health practices on the part of our rural residents.

The Place of the Physician In Rural Health Activities

PHR The physician's place in rural health activities is out in front. If physicians do not accept leadership in these activities—if they abdicate the role of guidance and direction which falls to them by training and responsibility—they forfeit not only a share of their influence, but also the right to criticize and judge the efforts of laymen who do interest themselves in this important field.

The rural health picture is not a single, simple one. It is a montage of many pictures, one that will vary from region to region, and from State to State. The whole environment of any given area—the climate, the soil characteristics, the stage of social and educational development, the types of landholding, and the level of transportation and communication—all these, and others, make up the facets of the greater picture.

The medical problem is not the only one in the rural health picture, and medicine alone—either in personnel or facilities—does not necessarily present the principal solution to these problems.

To illustrate, the doctors of the rural South, not so long ago, spent endless time treating

By Charles Reid Henry, M.D., chairman, rural health committee, Arkansas Medical Society, Little Rock.

pellagra. But when the whole health team—the laboratory nutritionist, the research chemist, teachers and leaders in information work, agricultural researchers, and the skilled field workers of the extension service—joined in the prevention of pellagra, it disappeared as a medical problem and as a health and economic factor. A great health program was overcome, not by bedside care—but by teamwork under medical leadership.

Of first importance in health activities, not only locally but at every level, is the attitude of the physician toward all the people and agencies available as allies in rural health efforts. The intelligent physician will let it be known that he welcomes all helpers in the field. He will not resent them as “busybodies,” or be contemptuous of the layman’s approach.

The typical physician—and the country doctor always—complains that he is terribly overworked, and can usually back up this complaint with facts and figures. But how often does he assess the whole situation around him which engenders his complaint? How well does he marshal others who might well lighten his load by helping to improve the circumstances—the larger health situation in which he works? Generally, the physician’s responsibilities in rural health activities are the same as those of any conscientious man interested in the welfare of his community, but the physician’s responsibilities extend further. In the smallest or unorganized communities, he may have to add to some degree the duties of sanitary engineer, epidemiologist, dairy and meat inspector, and quarantine officer. In larger communities, he will act as a watchdog to see that such functions are carried out faithfully.

Leadership Assignment

The mental curiosity and perception necessary to the successful completion of a medical education should naturally lead the physician to an awareness of health problems in his particular setting. He should further implement this awareness by sincere and eager cooperation with all the groups and agencies concerned with education, information, and community improvement. He should equip himself with a

knowledge of techniques used successfully in other areas to uncover and attack such problems.

In Arkansas we have proved at our rural health conferences that the Extension Service, the Home Demonstration Council, the Farm Bureau Federation, the dental association, the public school administrators, and the Woman’s Auxiliary of the Medical Society are all waiting for the go-sign from the local physician. They are all willing to do the legwork, paperwork, and the doorbell ringing necessary to gather facts on community needs. They are almost unanimous in assigning the physician number one place in planning and directing such activities. They will do the work, but they feel lost without his leadership and advice.

If the physician feels unequipped to exercise such leadership and to advise soundly, it is his duty to get the information necessary to initiate such activity, either from his State society rural health committee, from the American Medical Association, Council on Rural Health, or from libraries.

Planning and advising are not enough. No one can take the physician’s place to speak with authority on medical matters; he cannot assign decisions and interpretations on such matters to nonmedical personnel, no matter how willing.

The physician must assume his personal share of information and educational activities. These will involve, in most instances, talks before groups eager to get sound information on subjects affecting their health and medical needs. Careful preparation of talks will pay good dividends, both in effectiveness and in good will. Farm people of today, whether cattle producers, members of home demonstration units or Future Farmers of America, are accustomed to technical information such as they see regularly in extension bulletins, farm and health magazines, and their newspapers. A grunt and an anecdote are no substitute for a factual well-organized talk enthusiastically given.

The Broader Area

He must not overlook his influence in increasing attendance and participation at regional or State rural health conferences. Probably more

than anyone else in the community, he can draft leaders who will bring back from such meetings the enthusiasm and the stimulation so vital to the spread of interest in these activities. He is, in a measure, the adhesive agent which binds the various community forces together in health matters. I cannot emphasize too strongly the almost militant willingness to help if only the physician will lead the way. The cooperation is readymade and all that is needed is the spark of physician interest.

State medical society officials, and especially members of State rural health committees, must see that information about rural health problems is spread to every local society and to every physician. The problem is not just one for "country doctors"—it is the concern, or should be, of every doctor in the State. The specialist, who receives patients from rural areas, has just as big a stake in the whole picture as has the general practitioner. His attitudes, his efforts become a part of the whole feeling of the people in his State in their appraisal of medicine and medical care.

Of course, the first duty of a physician is to his individual patients but more than that, it is the responsibility of his profession to safeguard the whole health and medical care situation as well as professional knowledge can do it.

Dental Aspects of Rural Health in Oregon

Editor's Note: Dean Noyes defined the major dimensions of rural dental problems and reviewed in some detail recent studies in Oregon. This "brief" excerpts from his paper a few of these significant findings and viewpoints which, as the author noted, may be of assistance to other areas.

PHR Dental rural health problems do not differ greatly in quality or type from those that are found in the urban areas, although there is some difference in the distribution of specific oral diseases in the country as compared with the larger

cities. Our greatest problem is presented by the relatively thin geographic distribution of people in rural areas, which makes it necessary to modify appraisal methods of rural dental health and the administration of treatment.

The techniques of recording the type or pathologic nature of dental disease among rural peoples are similar to that in the city, consisting of surveys using data collected by dentists, dental hygienists or trained lay persons; the records of dental practitioners; the clinical judgment of these practitioners.

When we appraise our preventive measures, we find our armamentarium is comprised of the same therapeutic measures used with respect to those who reside in the city. These include education for adult and child; through education, the dietary control of oral disease of both the hard and soft tissues, and the promotion of good oral hygiene; through the topical application of sodium fluoride, particularly for young people, and the introduction of fluorine into the water supplies, with resulting benefits to children. In rural areas these benefits are limited rather largely to the school population and the extent to which an individual or household can take advantage of this proven preventive measure.

The advantage of fluorine in the water supply lies to a great extent in the early age at which it has effect. In other words, if we were limited to the topical application, even though we might be fortunate enough to make these applications to all the children of school age, fluorine in the home water supply provides the forming teeth of the child from birth to school age an advantage of even a greater degree of immunization.

I should like to mention, as well, the importance of early dental care. We may from time to time prevent serious problems if we take care of the little defects, and we can prevent serious and costly dental operations if we take care of the little things as the individual grows to attain maturity.

Now if we turn to the matter of treatment in rural areas, we find the same basic personnel as

By Harold J. Noyes, D.D.S., M.D., dean, University of Oregon Dental School.

Rural Demand for Dental Service 2,000 Inhabitants

in the cities except that here the personnel itself is spread over a wider area and the opportunity for choice of a dentist and the use of auxiliary personnel is far more limited. There are, of course, dentists who practice in small towns and the smaller metropolitan areas that are adjacent to farm and ranch country. In some cases, though far less than I would have expected, there is use of a dental trailer, which returns us to the itinerant dentists of the days of my grandfather, at which time it was not uncommon to have the dentist go around on horseback, or in a light wagon.

Dentists in metropolitan areas also have many rural patients, some of whom make it a business to come to the city periodically for dental care. Others combine dental attention with other business which they have in the city. This is difficult to arrange, particularly for young children, and it has other disadvantages. Auxiliary personnel—dental hygienists and dental assistants—likewise abound to a greater degree in the more heavily populated areas.

Rural Needs for Dental Care

No clear line can be drawn between the rural and urban need for dental care. Nevertheless, people who live outside of corporate limits have a great handicap in access to dental personnel. Analysis of the dentist-to-population ratio in urban and rural counties of Oregon reveals a distinct difference.

Similarly, we must recognize the very real distinction between the needed amount of dental care and that demanded by a given community. Dental care must be considered in its proportional relation to general health, and the cost of complete dental care of the residents of Oregon would require the expenditure of approximately \$73,178,475 for the accumulated dental defects which exist at the present time. The annual cost of complete care for each year's increment of dental ills will approach if not exceed \$22,581,061. If there were dental personnel to provide these services, which there is not, the expenditure alone would be unwise if not impossible.

There exists a very real correlation between dental care purchased and the per capita income of the community. A similar relation, though less positive, exists between the educational level of a population and the willingness to procure dental services.

Effective Demand in Oregon

What, then is the effective demand in Oregon for dental care? The net income of 54.2 percent of the 61,188 farms in Oregon in 1945 is reported to be below \$1,500 annually. Persons who receive half of the necessities of life from their produce may be expected to purchase little more than emergency dental care. Of the remaining 45.8 percent no less than 10.7 percent will refuse all but emergency care, leaving but 35.1 percent who will have the means and in-

Urban Demand for Dental Service

clination to seek complete or nearly complete dental health service.

To deserve his consideration as a vocation among those open to young men and in order to make a livelihood which compensates him for educational expenditures a dentist must have approximately 700 patients that require his services for more than emergency care. Thus a dentist who is looking for a location in a rural community in the State of Oregon cannot consider any situation which does not offer approximately 2,000 inhabitants unless the average family income expectancy is above \$3,000 annually. Under average conditions he can postulate that 1,084 persons will not be able or willing to utilize his services for more than the relief of pain or occasional dental care; 916 will be able to do so, but of that number 214 will be unwilling to go beyond the extent of the first group; and he will have to rely upon the remaining 702 for his stable living (see "rural demand" chart).

In November 1952, there were 992 dentists licensed and practicing in Oregon, which has 1,521,341 persons (1950 census). This represents a ratio of one dentist to each 1,534 people. There are now 27 dental hygienists practicing in Oregon. A statement of this sort must be interpreted in terms of the availability of service to the individual who wishes dental care. In the urban area of Multnomah County, for example, the ratio is 1 to 935, while in Polk County it is 1 to 5,137, and in Sherman and Wheeler Counties, there are no dentists reported by the State Board of Dental Examiners.

Moreover, this does not mean that each person in Multnomah County has 1/935 care of one dentist. It means only that the persons who are willing to purchase dental service have attracted dentists to this area in that proportion. Why can a dentist find it to his advantage to serve in a 1/935 ratio in Multnomah County, when he cannot afford to risk location in most rural areas where he will be one dentist to 2,000 people? Because the segments of the circle are altered and the percentages changed in the urban area of Portland (see "Urban demand" chart).

The 35.1 percent who have the resources and

desire for dental care extend into the 10.7 percent that will not seek dental care. Moreover the 35.1 percent are sufficiently convinced of the value of this service that they will pay a higher premium for it. This means offering a greater bid for dentists than the same segment of rural population. Also, the 54.2 percent who feel that their circumstances justify only emergency care and limited service is transformed in part by dental health education and public social acceptances in such manner that they feel dental services deserve greater priority in their limited budget.

The Manpower Problem

Of the 992 practicing dentists in Oregon we can expect to lose 24 in 1953, if we accept the actuarial figure of O'Rourke (see chart). We may expect to lose, as well, 21 dentists who will leave Oregon to locate elsewhere. Anticipating that 75 percent of the Oregon residents whom we graduate in June of 1953 remain in the State of Oregon, we will increase our total by 35, and probably gain at least 5 Oregon graduates from out of State. We have the added opportunity for improving our ratio and compensating for such increase in population as may take place in the current year through the number of dental graduates from other dental schools who pass our State Board dental examinations and remain to practice in this State, estimated at 14. We could therefore expect to have 1,001 dentists in 1954, unless those taken by the Armed Forces are not replaced by veteran dentists who return to Oregon to practice.

Amplifying Service

There are additional ways in which the available volume of dental service may be amplified. The use of auxiliary personnel—dental hygienists, assistants, technicians—effectively increase the productivity of the dentist. Related is the use of two-chair offices and modern equipment, and of late very interesting studies have pointed to the increased hours of service they permit.

The data are irrefutable with respect to our ability, if we would utilize our present knowledge, to reduce materially the incidence of dental disease in children. It is possible where the

diet of a child can be controlled in an institution to practically prevent dental decay. Under present existing diets in the average home and with the almost insatiable desire which both children and adults have for sweets, this has not been practical in private homes. We should not, however, blame the dental profession for our inability to follow a dietary regimen which if implicitly pursued will make cavity formation negligible.

Likewise there is good reason to believe that the incidence of dental decay in children up to the age of 15 can be reduced approximately 40 percent by the topical application of sodium fluoride if the procedures advocated by the United States Public Health Service are pursued. However, the cost in the terms of a dentist's hours of time in applying sodium fluoride in his own office is about equivalent to that which would be required if he were to restore by fillings the cavities which he prevents. Here the use of a dental hygienist operating at a lesser hourly cost in the fabric of the public school system can perform a very important service.

We should not be misled, however, by thinking that a reduction in dental service required by children is a reduction in ultimate demand for care over the entire life span. While it is certainly important from the standpoint of esthetics and function and the effect which the latter has upon health, we must recognize that the retention of teeth may increase the problems which come from disease of their supporting tissues in the later years of life. We cannot,

therefore, look at preventive measures in childhood in any great degree as a reduction in the overall burden upon dental care.

It is conservative to say that at least 10 percent of the need for dental care could be eliminated if the public would practice conscientiously and consistently the procedures which are presented in the literature and provided in the schools and follow the advice that is given in dental offices and in the programs which are promulgated by units of the dental profession and the State departments of public health.

To document this estimate: a 3-year dental health education program in Greenville, Tex., resulted in a rate of 9.9 missing permanent teeth per 100 children. In comparison, Jacksonville, Tex., where no dental health education was operating, there were 26.2 permanent teeth missing per 100 children.

If We Applied What We Know . . .

On the basis of national survey data, about half of the 992 Oregon dentists are now using two-chair offices, and about 64 percent employ dental assistants. The effect of full utilization of these resources would be to add 297 dentists to the total dental service rendered Oregon.

If we could develop effective measures in dental health education, it would relieve the burden on the dentists who are practicing in the State to an extent equivalent to adding 99 dentists to the overall total. Finally, if we were to save the operating time of 992 present practicing dentists by using dental hygienists

for the limited operations they are licensed to practice, we would in effect add 193.

In other words, applying tested procedures would change the effective impact of 992 dentists to a condition equivalent to having 1,581 and would reduce the present dentist population ratio from 1 to 1,534 to 1 to 962 (see chart).

To Increase Rural Care

There are several practical ways to increase rural dental services in Oregon. First, encourage local residents to study dentistry. There is a tendency to return to the area of residence for professional practice. This should be fostered, as should the challenge that dentistry offers in the field of human service.

Second, support the State department of public health, whose dental health officer can facilitate dental health education, stimulate dental health service programs, and implement local district dental societies.

Third, support the State dental school. If we are to meet our obligations and assist in the provision of increasing dental care in the rural and urban areas alike, we must continue

our progress in increasing the number and the quality of dental school graduates. At the same time, it is essential that through the study of public health problems and energy directed in dental research that assistance be offered in the distribution of dental service and in the perfection of measures and technics which decrease the volume of dental ills.

Fourth, support local dentists. Earnest, conscientious professional men cannot exist nor can young men be encouraged to come to rural areas unless they can have the professional satisfaction of performing a comprehensive health service. They will be glad and willing, I am sure, to assist in the relief of pain, to perform extractions and emergency dental care and to construct full dentures, but if the rural areas are to compete with those of the larger cities in their bid for dentists it will be necessary to provide these men with the opportunity to administer dental service as a true health service and not on a basis of selling their wares over the counter upon the prescription of the patient, who is in no way qualified to make his own diagnosis or prescribe the expedient treatment.

Department of Health, Education, and Welfare Created

The Federal Security Agency became the U. S. Department of Health, Education, and Welfare on April 11, 1953. On the same day, Mrs. Oveta Culp Hobby was sworn in as the first Secretary of the newly created executive Department. Her nomination to the cabinet post was unanimously confirmed by the United States Senate on the previous day. Mrs. Hobby took office as Administrator of the Federal Security Agency on January 21, 1953.

As one of her first appointments, Mrs. Hobby named Park M. Banta of Arcadia, Mo., to the post of General Counsel. Mr. Banta replaces the former General Counsel of the Federal Security Agency, Mr. Alanson W. Willcox. After serving in the 80th Congress from the Eighth District of

Missouri, Mr. Banta practiced law in Ironton, Mo. Prior to his election to Congress, he served as administrator of the Missouri State Social Security Commission from 1941 to 1945.

Also, Mrs. Hobby has appointed Mrs. Jane Morrow Spaulding of Charleston, W. Va., as Assistant to the Secretary of the new Department. Mrs. Spaulding's wide experience in social welfare work includes service as State director of Negro relief for the West Virginia Relief Administration and the founding of the only private child-caring institution for Negro children in West Virginia. Mrs. Spaulding succeeds Mrs. Anna Arnold Hedgeman, a former assistant to the Federal Security Administrator.

Climate and Endemic Dental Fluorosis

By DONALD J. GALAGAN, D.D.S., M.P.H. and GLENN G. LAMSON, Jr., A.B.

INVESTIGATIONS demonstrating the relationship between trace amounts of fluoride in community water supplies, the prevalence of mottled enamel, and a reduction in dental caries experience have been extensive during the last half century. By 1931 it had been determined that mottled enamel was associated with the presence of fluoride in drinking water (1, 2). Subsequent studies revealed the direct quantitative relationship between fluoride and mottled enamel (3-6) and demonstrated the inverse relationship between fluoride and dental caries experience (7).

Based upon these data, using the community fluorosis index to measure the extent of mottled enamel (8), and the decayed, missing, filled (DMF) index as a measurement of caries experience (9), an optimum fluoride concentration was derived for use in the supplementation of fluoride-deficient community water supplies. The range of fluoride concentration most effective in preventing dental caries was established at approximately 1.0 to 1.5 ppm, well below the critical point in the causation of mottled enamel.

A review of the literature reveals that the recommended fluoride levels have been determined from observations made within a fairly limited geographic area, principally in the Midwest (10) where mean annual temperatures are approximately 50° F.

Temperatures in the continental United

States vary widely, from an average mean annual temperature of 40° to 45° F. in the northern tier of States to 70° F. and above in some areas of California, Arizona, Texas, Louisiana, and Florida (fig. 1).

In view of the temperature distribution in the United States, a fluoride concentration of 1.0 to 1.5 ppm seems justifiable for the major portion of the country. However, Arnold (11) has suggested that because of climatic conditions 1.0 to 1.5 ppm of fluoride may not be practical or desirable in every community, and Dean has recently indicated that less than 1.0 ppm of fluoride may represent the optimal level for dental caries control in a southern community (12). The early findings of the Smiths (13, 14), while not relating mottled enamel to climatic factors, certainly suggest that mild fluorosis is associated with less than 1 ppm of fluoride in certain areas in Arizona.

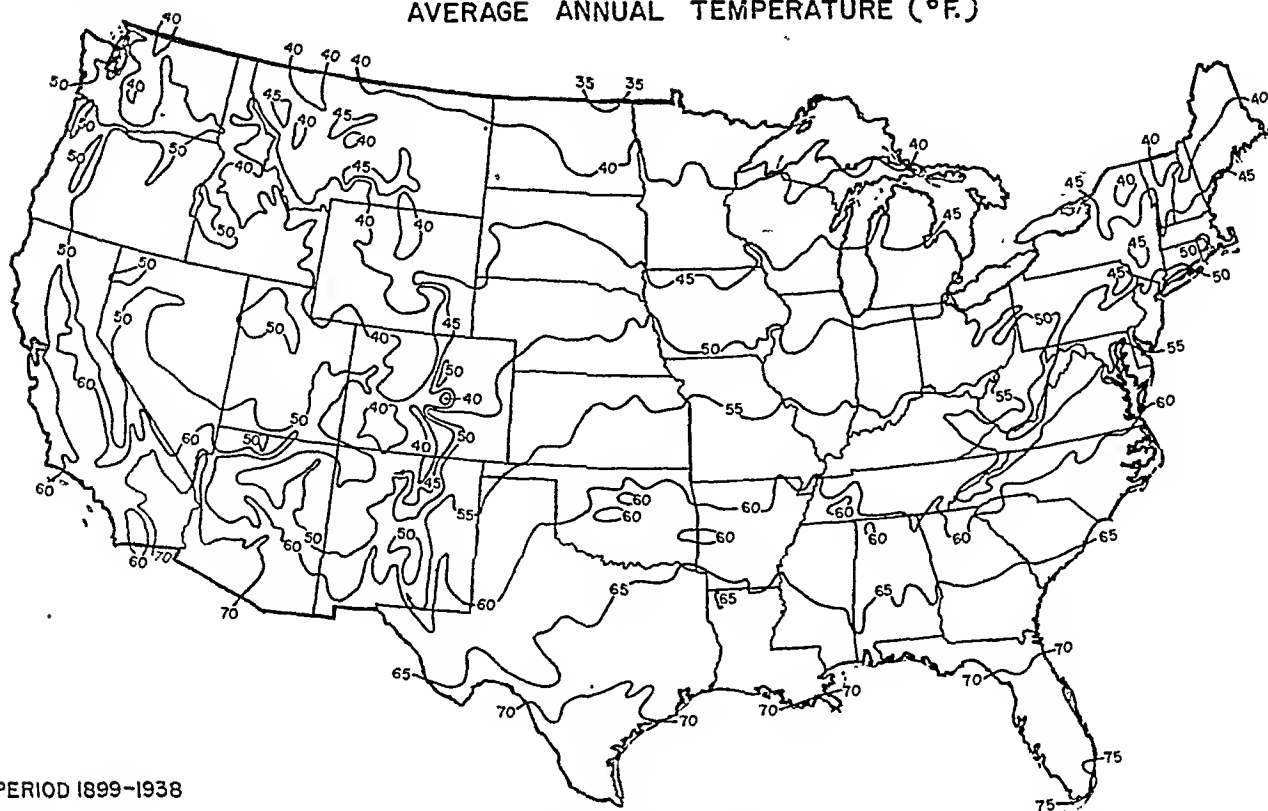

Recognition of a probable relationship between fluoride concentration and climate is being observed in the present fluoridation effort. For example, in the State of Wisconsin, 1.3 ppm is recommended. In Charlotte, N. C., the concentration of fluoride is varied from a high of 1.2 ppm in winter to a low of 0.6 ppm in summer, and in Florida, 0.7 ppm is the recommended optimum amount. Nevertheless, if climatologic factors markedly influence the water intake of infants and youth, additional information about optimum concentrations should be obtained for those exceptional areas experiencing extreme climatic conditions.

Since the severity of mottled enamel has a specific relationship to the fluoride content of water consumed, the application of a simple biological test such as a measurement of fluorosis

Dr. Galagan is the regional dental consultant assigned by the Public Health Service to Region X, San Francisco, Calif. Mr. Lamson was formerly a health program representative assigned to that region.

Figure 1. Variations in temperature throughout the continental United States, 1899-1938.

AVERAGE ANNUAL TEMPERATURE (°F.)

may be used to evaluate water intake indirectly. In order to use this method of assessing climatic forces upon water intake, it seemed logical to measure fluorosis in communities with extreme temperatures. If objectionable fluorosis was not associated with fluoride levels around 1.0 ppm in the areas with extremely high temperatures, then that concentration would be desirable in the supplementation of fluoride-deficient water in areas with similar climate, and at least that amount would be required in all other parts of the United States.

Field Studies

The Arizona communities of Yuma, Tempe, Tucson, Chandler, Casa Grande, and Florence were selected for initial study. With the exception of Yuma these communities lie south and east of Phoenix on the plains of the Arizona Desert. Yuma is situated on the Yuma Desert on the northern edge of the Great Desert of Sonora, Mexico.

These six communities met the necessary re-

quirements for investigation. They had water supplies with adequate continuity and with fluoride concentrations ranging around 1.0 ppm. They were of sufficient size to yield a sample of native-born children large enough to be significant (15). They had mean annual temperatures ranging from 67° to 72° F., with an average mean annual temperature of approximately 70° F. This area is consistently reported as one of the hottest inhabited areas in the United States, exceeded in temperatures only by certain communities adjacent to Death Valley, Calif.

Public Water Supplies

The general characteristics of the water systems of the six study communities are shown in table 1. The data on fluoride determinations of the common water supplies of the six communities are presented in table 2.

These data were available as samples taken from individual wells and from the general distribution system after pooling. The arithmeti-

Table 1. Characteristics of the common water supplies in six Arizona communities, 1935-51

Community	Source of supply	Treatment

Tucson-----	17 wells-----	Chlorination; ammoniation.
Chandler-----	4 wells-----	None.
Casa Grande--	5 wells-----	Do.
Florence-----	4 wells-----	Do.

cal mean of all available analyses of individual well water and of finished water has been accepted as the figure most nearly representing the fluoride concentration of the several water supplies. They represent analyses made intermittently from 1935 through 1950 and quarterly during 1951. The fluoride concentrations range from 0.4 ppm at Yuma to 1.2 ppm at Florence.

A more detailed description of each of the water supplies follows.

Yuma. The public water supply of Yuma has been obtained from the Colorado River since 1892. The treatment plant in current use was put into operation in 1945. The first treatment starts about 18 miles above Yuma, where a desilting plant is located. The main treatment plant is situated on the Arizona bank of the Colorado River in Yuma proper. A 4,500-gallons-per-minute turbine pumps water directly into the first settling basin in the plant. A second turbine, with a 5,000-gallons-per-minute capacity, pumps water from the Bureau of Reclamation canal, 1,200 feet away. Treatment at the plant consists of the addition of aluminum and copper sulfate, flocculation, filtration, and chlorination. Storage is obtained by means of two 500,000-gallon reservoirs from which the water is pumped into the distribution system.

(In the summer of 1937, sewage backed up in the Colorado River, and the water became unsafe for drinking purposes. During a 3-month period water from the City Park well, normally used to supply the municipal swimming pool, was pumped into the distribution system and supplied the water for the community. No data are available indicating the fluoride concentration of the well water at the time it was used for drinking purposes. but a

sample of the water as of May 12, 1951 showed 0.6 ppm.

The mean of 79 fluoride determinations shows the Yuma water supply to have a fluoride concentration of 0.4 ppm.

Tempe. During the study period the water for the community of Tempe was obtained from four wells. These wells, established in 1894, were located side by side, were pumped by a single piston, and were approximately 140 feet deep. No data are available to show whether they were cased, but the local waterworks operator thought they probably were not.

Finished water is stored in a 1,000,000-gallon tank. Chlorination was instituted in 1939; no other treatment is given. The average fluoride concentration for the common water supply is 0.5 ppm.

Tucson. The city of Tucson presented a special investigative problem. The water supply for the community is derived from more than one source, and is distributed through two systems, the Northside system with a fluoride concentration of about 0.3 ppm. and the Southside system with a fluoride concentration of 0.7 ppm. This study was concerned exclusively with the area served by the Southside system and hereafter will be the one under consideration.

The water for the Southside system is obtained from ground water in the Santa Cruz River basin. It is produced from 17 wells located south of the city on the east bank of the river (dry). The water from these wells is pumped into a 30-inch concrete conduit which carries it to two reservoirs, with

Table 2. Reported fluoride concentration of water from all available single source and distribution system samples in six Arizona communities, 1935-51

Community	Number of samples	Mean fluoride content

Tempe-----	7	.5
Tucson-----	31	.7
Chandler-----	16	.8
Casa Grande--	20	1.0
Florence-----	22	1.2

SOURCES: University of Arizona, College of Agriculture, Agricultural Experiment Station, Tucson, Ariz.; U. S. Department of Agriculture, Bureau of Plant Industry, Soils and Agricultural Engineering, Salinity Laboratory, Riverside, Calif.

1,500,000- and 7,300,000-gallon capacities, respectively. The water is chlorinated at a point in the conduit before arriving at the reservoir. This is followed by ammoniation at 0.05 ppm.

Fourteen of the 17 wells were in operation prior to 1930. Two additional wells were placed in use in 1946, one in 1947. The wells are pumped alternately in the winter; in the summer, when demand is greater, all wells operate most of the time. The first 6 wells sunk are 125 feet deep. The remaining 11 extend from 200 to 300 feet in depth. Their individual output varies from 300 to 1,300 gallons per minute, with a total capacity of 9,000 gallons per minute.

Since 1938, when a set of control valves was installed to separate the two systems, no water has passed from the Northside into the Southside system. Prior to 1938, small amounts of water may have passed from the Northside into the Southside system. Since the fluoride concentration of the Northside system is the lesser of the two, the contamination of the water under investigation, if any, would result in a lowered fluoride concentration.

Only children who had continuous exposure to the common water supply of this community within a community were included in the study group. A buffer zone of three to five blocks was set up within the limits of the Southside system. Children were excluded from the study if they had lived in or beyond the buffer zone at any time. The normal range of a child at play probably is not greater than that; consequently, exposure to fluoride concentrations less than that of the Southside system would be casual.

The broken line on the map of the city of Tucson (fig. 2) shows the limits of the Southside water system as of 1935. The solid line indicates the area from which the study children were selected.

Chandler. During the study period the water supply for the city of Chandler has been produced by four wells. The initial two wells, 335 and 987 feet deep, were drilled and put into operation in December 1926. Both wells drew water from the 300- to 325-foot level, the depth at which they were perforated. In 1938 the casing above the perforations broke, and a considerably harder water began to enter the wells. Because of this, two new wells were put into operation, one in 1944 and one in 1948. They are both 650 feet deep, perforated from the 360-foot level to the bottom. The original wells were scaled off in September 1944.

The arithmetical mean of the fluoride determinations made while the original wells were in use is 0.75 ppm; of those made subsequent to that date, 0.85 ppm. The single analysis available for the period during which water was entering the wells from above the perforations indicates that the fluoride concentration at that time was 0.8 ppm the same as the numerical average for all observations. It seems clear that the fluoride concentration of the common water supply has remained constant during the study period.

Casa Grande. The water for Casa Grande is obtained from five wells, which were put into operation in 1922, 1930, 1937, 1946, and 1950. The location of each new well site was moved consistently to the northeast to get better water, but they are in fairly close proximity, all but one being within the city limits. The wells range in depth from 210 to 302 feet, with the exception of one 759-foot well which is used for emergency purposes only. No data were available as to the depth of the perforations in the well casing.

The wells have a total rated output of 1,700 gallons per minute with an average reported daily output of 594,000 gallons. The water is stored in a ground level storage tank of 500,000-gallon capacity and in an elevated tank holding 100,000 gallons. It is not treated.

The new wells added to the system during the present study do not seem to have changed the fluoride concentration of the water supply. Samples from the distribution system have ranged from 0.9 ppm to 1.2 ppm of fluoride. Twenty analyses, for the years 1931 through 1951, are available, representing all seasons of the year. The numerical average of all available fluoride concentrations reported for samples taken from the system and from individual wells is 1.0 ppm.

Florence. During the study period the community of Florence has obtained its water from four wells. The two original wells, 180 and 190 feet deep, were put into operation in 1919. A new 400-foot well, perforated the last 40 feet, was put into operation in 1939, and the two old wells were closed. Because of increased demand, another 400-foot well, perforated at the same level, was put into operation in July 1947. The new and the original wells are adjacent to each other within the city limits.

The wells now in use have a rated output of 350 gallons per minute, and an average daily output of

Figure 2. Map of the city of Tucson, Ariz., showing outline of Southside water distribution system, buffer zone, and area from which study children were selected.

386.5 thousand gallons per day. The water is not treated. Overflow is stored in a 55,000-gallon elevated standpipe.

Since there was a complete change in well usage during the early part of the study period, the available fluoride concentrations have again been divided into those taken prior to the date the old wells were closed, July 1939, and those taken after that date. A total of 21 fluoride analyses, with a numerical average of 1.2 ppm, was reported during the study period. Fourteen of the samples were taken prior to July 1939, and 7 were taken

after that date. Both average 1.2 ppm of fluoride. It seems evident that the fluoride content of the Florence water supply was not altered by the change in wells.

Materials and Methods

Since these studies were designed to determine the extent of dental fluorosis in children with continuous exposure to common water supplies containing low fluoride concentrations, it was necessary to get accurate information regarding the water history of the children

Table 3. Percentage age distribution of 726 children examined in six Arizona communities, 1951

Number of children in each community	Age (years) and percent in each age group							
	9	10	11	12	13	14	15	16

Tempe (113)-----	5	13	16	18	11	12	13	12
Tucson (316)-----	3	7	8	11	18	24	17	12
Chandler (95)-----	8	15	14	20	15	9	12	7
Casa Grande (50)-----	8	12	22	12	18	14	8	6
Florence (70)-----	3	9	9	16	18	14	20	11

studied. The following screening procedure was adopted in each community:

Screening Step 1. Public and parochial school children from the fourth through the ninth grades were each issued a card which asked the following questions:

Were you born in this town?

Have you lived here all your life?

Have you been away from this town for more than 30 days in any 1 year?

This initial screening served to eliminate those children obviously not continuous residents of the community.

Screening Step 2. Each child who indicated that he was born in the community and had lived there all his life was given a questionnaire to take home to his parents or guardian, with an explanatory letter. The parents were requested to record the birthplace of the child, the addresses of all his residences, continuously and in sequence, from birthdate to date of the questionnaire, and the source of the water used for drinking and cooking purposes at each residence. They were also asked to describe specifically the absences of the child from the community for more than 30 days.

Screening Step 3. Children who passed through the first two steps were scheduled for dental examination. At the time of examination, each child was questioned by a dentist or a dental hygienist to verify the information obtained in steps 1 and 2. A school or public health nurse was present to add her knowledge of the home situation to the water history data.

Screening Step 4. If the data obtained in any of the first three steps was inconsistent the parent

was interviewed by a member of the survey team and was asked to clarify the discrepancies.

Only children who had consumed water from the common municipal supply continuously from birth through their ninth year were included in the study. Children who experienced interruption in the continuity of consumption of the community water for periods of more than 30 days in any one calendar year were excluded. The remaining children served as study material.

Clinical Examinations

All dental examinations were made by the same examiner. The children were seated in a portable dental chair; and a mouth mirror, a Burton light, and compressed air were available for the examiner's use. Each tooth was assigned a fluorosis classification according to Dean (8). The tooth-unit fluorosis classification was later transposed into child-unit classification for use in computing the community fluorosis index. The percentage age distribution of the 726 Arizona children examined is shown in table 3.

Findings

The data relative to the prevalence and severity of fluorosis obtained in the six communities are presented in table 4. The occasional child falling into the moderate or severe classification when exposed to relatively low fluoride concentrations is worthy of note.

The community fluorosis index may be used for an objective measurement of the extent of endemic dental fluorosis. The direct relationship between fluoride concentration and fluorosis noted in prior investigations is evident. As the fluoride concentration rises the community fluorosis index is increased and the number of children without visible fluorosis is reduced. The community fluorosis index ranges from 0.21, associated with 0.4 ppm of fluoride at Yuma, to 1.12 for Florence which has 1.2 ppm of fluoride in its water supply.

Comparison With Midwestern Indexes

To compare possible variations in the intensity of dental fluorosis under different climatological conditions, data obtained from 10 com-

Tucson.....	.7	316	53	120	143	38	10	5	-----	.46
Chandler.....	.8	95	18	40	37	9	6	2	1	.52
Casa Grande.....	1.0	50	24	7	19	15	9	-----	-----	.85
Florence.....	1.2	70	39	17	14	18	10	9	2	1.12

munities with similar fluoride concentrations were selected from the study of "21 cities" by Dean and his co-workers (10). The communities in the 21 cities group, which may be considered as a base line, have a mean annual temperature of approximately 50° F., whereas the six communities in Arizona have a mean annual temperature of approximately 70° F.

Data on the prevalence and severity of fluorosis in both groups of communities are presented in table 5.

Comparison of the data reveals that the Arizona communities have a somewhat higher percentage of children affected by fluorosis than communities with a cooler climate and comparable fluoride concentrations in their water supplies. There is also a wider distribution throughout the fluorosis classification. Some of the Arizona children present moderate to severe fluorosis associated with exposure to less than the generally recommended fluoride concentration of 1.0 ppm.

Dean has stated that a community fluorosis index below 0.4 is of little or no public health concern. He considers the range from 0.4 to 0.6 as borderline. For indexes above 0.6 the removal of excessive fluorides from the water is recommended (8). From table 5 it may be seen that the fluorosis indexes for communities with fluoride concentrations above 0.5 ppm are considerably higher in the Arizona communities. Yuma, Ariz., and Marion, Ohio, both have fluoride concentrations of 0.4 ppm and fluorosis indexes of 0.21 and 0.25, respectively.

As the fluoride concentration rises, the disparity between indexes becomes marked, so that Florence, Ariz., and East Moline, Ill., with fluoride concentrations of 1.2 ppm, present fluorosis indexes of 1.12 and 0.49, respectively.

The fluorosis indexes for the two groups of communities have been plotted on figure 3.

The least squares method was used to calculate the index lines. (Trend line formula for 70° F. communities is $y = -0.291 + 1.132x$ and for 50° F. communities is $y = 0.021 + 0.353x$.) The line for the Arizona group has a much steeper slope than that representing the midwestern communities. The index line for the Arizona communities accelerates at approximately twice the rate as the one for the midwestern communities. The line for the midwestern cities crosses from the negative area into the borderline zone at approximately 1:1 ppm and from the borderline into the objectionable zone at 1.7 ppm. On the other hand, the line for the Arizona communities crosses from the negative area into the borderline zone at 0.6 ppm and into the objectionable zone at 0.8 ppm.

These data would indicate that the children residing in the Arizona communities under consideration develop twice as much fluorosis as midwestern children when exposed to water containing the same concentration of fluoride. (It should be noted that the two groups of children were diagnosed by different examiners. The data are therefore subject to the error of examiner differences.)

Climatological Variables

About two-thirds of man's total fluid intake is water, the remainder, other fluid substances. Except for temporary circumstances of an emotional nature, the amount of fluid ingested is determined by water deficiency. Every bit of body water lost must be replaced, and the replacement amounts are obligatory. (In growing children fluid intake may be slightly greater than water loss since some additional water is needed to build new tissues, but generally speaking, water intake and water loss will be equal over a 24-hour period.)

Temperature

Excessive temperatures result in a bodily demand for fluid over and above that usually

required for normal physiological processes (16). When environmental temperatures rise above skin temperature (92° to 95° F.), the only method by which the body can cool itself is vaporization. Heat loss can no longer be effected by radiation or conduction. The water output of the body is therefore increased in proportion to the need for increased vaporization. It follows that there will be an equal increase in the amount of water ingested in order to maintain body water balance.

The extremely high temperature occurring in the southwestern communities is undoubtedly a major factor contributing to the increased severity of endemic fluorosis observed in the Arizona children through its influence on water consumption. Some indication of the differ-

Source: Table 5.

ence in temperature between the two geographic areas is reflected in their mean annual temperatures of 50° and 70° F. (table 6).

Temperature Range

The mean annual temperature is a simple measure of the climatic conditions to which man is exposed. It is the mean of the daily high and low temperatures for a year, and does not critically reflect differences in daytime and nighttime temperatures.

During most of their tooth-forming years children are active almost exclusively during daytime hours. Consideration of mean temperature alone may therefore result in an underestimation of the actual temperatures to which they have been exposed in warm, semi-arid climates. Comparisons of temperature ranges may reflect more clearly the real difference in temperature experienced by the chil-

dren residing in two geographic locations. The data on mean maximum and mean minimum temperatures and the temperature ranges for the Arizona communities under consideration, and for the midwestern communities (or representative communities if complete weather data for each city were not available) are also presented in table 6.

Although the difference between the mean annual temperatures of the two groups of communities is considerable, the difference in the range of high and low temperatures, or day and night temperatures, is even more marked. The midwestern communities have an average range of 22° F. between the daytime maximum and the nighttime minimum, whereas the Arizona communities have an average range of 33° F. Daily variations are considerably greater in any semiarid area (17), and daytime temperatures well above 100° F. are common

Developing Trends and Standards of Sound Drug Therapy

—A Symposium of the AAAS—

The role of the United States Pharmacopeia, the National Formulary, New and Nonofficial Remedies, and Accepted Dental Remedies in developing and maintaining sound drug therapy trends and standards was the subject of a symposium at the annual session of the American Association for the Advancement of Science in St. Louis, December 1952.

The symposium, at which spokesmen for the four met to discuss this topic for the first time, was held at the joint session of the Association's subsection on pharmacy and its scientific section with the American Pharmaceutical Association, the American Society of Hospital Pharmacists, the American Association of Colleges of Pharmacy, and the American College of Apothecaries.

Mr. Linwood F. Tice, dean of the Philadelphia College of Pharmacy and Science, presided. Dr. Lloyd C. Miller represented the United States Pharmacopeia, Dr. Justin L. Powers, the National Formulary, Dr. R. T. Stormont, New and Nonofficial Remedies, and Dr. J. Roy Doty, Accepted Dental Remedies.

By a special arrangement with the Association and the American Journal of Pharmacy, Public Health Reports is presenting somewhat condensed versions of the five symposium papers. Comments on the symposium made by Mr. Louis C. Zopf, representing the schools of pharmacy, are also included.

Standing (left to right): Mr. Linwood F. Tice and Dr. Lloyd C. Miller. Seated: Dr. Justin L. Powers, Dr. Robert T. Stormont, Dr. J. Roy Doty, and Mr. Louis C. Zopf.

A Public Responsibility

By LINWOOD F. TICE, Ph.G., M.S.

Pharmacists and physicians in the United States often overlook the unusual but fortunate situation which we enjoy concerning the establishment of drug standards. In most countries, a pharmacopeial commission is selected and

Mr. Tice, professor of pharmacy and dean of the Philadelphia College of Pharmacy and Science, acted as panel moderator. Mr. Tice is also a member of the revision committee of the United States Pharmacopeia.

empowered by the government to choose drugs warranting official recognition and to establish their standards for purity and strength.

In this country, a group of experts, the Committee of Revision of the United States Pharmacopeia, are selected by and from those physicians, pharmacists, chemists, and pharmacologists who represent all organizations having a recognized interest in drug standards. These experts are elected by a democratic process at each Decennial Convention of the United States Pharmacopeia. They, then, serve until their successors are elected at the next convention.

The National Formulary Committee, likewise, is composed of experts selected by the American Pharmaceutical Association without political or governmental interference.

The Congress has recognized the finished work of these two groups—the United States Pharmacopeia and the National Formulary—as establishing the legal standards for drugs in the United States. Supplementing these two books of legal standards are New and Non-official Remedies and Accepted Dental Remedies. The former represents those drugs meeting the qualifications as to nature, use, claims, and so forth imposed by the Council on Pharmacy and Chemistry of the American Medical Association. Accepted Dental Remedies lists those meeting the requirements of the Council on Dental Therapeutics of the American Dental Association.

These four books, U.S.P., N.F., N.N.R., and A.D.R., are true examples of democracy in action and ones of which we, as a free people, can rightfully be proud.

As in all democratic institutions, however, freedom imposes with it a responsibility, and those who help establish policy and guide the affairs of these books must keep this great public responsibility constantly in mind. Each of the five symposium members is intimately concerned with one of these official or standard books and the policy and program governing them. Each is, in fact, a key individual concerned in each instance. That each one has recognized his responsibility not only to the public but to the professions concerned in this work is evidenced by his presence at the symposium.

The United States Pharmacopeia

By LLOYD C. MILLER, Ph.D.

Specifying standards of quality and purity for drugs, the United States Pharmacopeia is published every 5 years by a permanent organization which was first created in 1820. The organization consists of a board of trustees, a panel of officers, a permanent secretariat, and a revision committee of 60 experts.

Members of the revision committee are selected for their knowledge of all branches of medicine, chemistry, and pharmacy which conceivably can contribute in an important way to the technical work of revising the list of drugs included in the Pharmacopeia and their standards. The work of the committee is organized and directed from permanent headquarters in New York City.

The revision committee consists of 20 experts in medicine and 40 experts from the pharmaceutical and allied professions. The primary responsibility of the 20 physicians is to determine what drugs represent the best practice and teaching of medicine. It is the responsibility of the 40 other committee members to determine how pure and potent these drugs shall be and to provide methods by which these qualities may be determined.

Of course, the specifications vary according to the nature and end use of the drug. A crude drug used as the starting material of a pharmacopeial item is far different from a drug intended for intravenous administration.

The Pharmacopeia must concern itself not only with the quality of the drug but with its packaging and storage so that its initial quality will not be modified. This concern extends, of course, to the nature of the containers and the length of time the drug is safe for use if it is subject to deterioration.

The Pharmacopeia has other ancillary functions, but its main purposes are to determine

Dr. Miller is director of revision, United States Pharmacopeia, New York City.

what drugs shall be given pharmacopeial status and how pure must these drugs be.

U.S.P. Function

How much does the United States Pharmacopeia influence drug therapy trends now?—is a question which defies answering in definite terms. An answer is important in determining whether the Pharmacopeia is doing enough or might do more. This question has never been made the subject of an opinion poll, nor is it likely to be, but a fairly sound estimate is possible by looking closely at these accepted facts:

1. The official (United States Pharmacopeia and National Formulary) drugs are emphasized in teaching students of medicine and students of pharmacy. Their familiarity with the official drugs is bound to increase the use of U.S.P. drugs. Conversely, drugs which do not have official listing are less favored because they are less well known.

2. The official drugs are of a standard quality which is not subject to unannounced changes dictated by whim or trivial considerations. Only after careful study and often extensive investigation in the laboratory are revisions in the U.S.P. standards made.

3. Within limits imposed by the patient's need, the official drugs are the agents of choice in those cases covered by such health insurance plans as the Blue Cross. Many health insurance contracts call for payment only for the official drugs. In some ways, this represents a handicap imposed for convenience, but it gives the United States Pharmacopeia a real responsibility. The branches of the Government which procure drugs in quantity—the Armed Forces, the Public Health Service, and the Veterans Administration—all draw heavily upon the United States Pharmacopeia.

4. The official drugs are generally less expensive than the nonofficial drugs because most of their research and development costs have been charged off over the years since their introduction. Relatively few of them are subject to patent control so that all the forces of competition are brought to bear on keeping down the cost of manufacture and distribution.

5. Under the new Food, Drug, and Cosmetic Act of 1938 as well as under the original act of

1906, the Congress directs the Food and Drug Administration to utilize the United States Pharmacopeia and the National Formulary to insure quality, purity, and potency of drugs moving in interstate commerce. In consequence, most of the individual States similarly direct their boards of pharmacy to use the official compendiums as the basis of their regulatory activities. It is an outgrowth of this adoption of the United States Pharmacopeia and the National Formulary that led to a serious complication. It arises from the fact that in many States the official drugs may be sold only under the direction of a qualified pharmacist. Strong forces are working to extend the marketing outlets of many well-established drugs so that they may be sold, for example, in grocery stores. Since obviously few grocery stores are interested in employing a pharmacist, there is much pressure to modify existing "restrictive sales" provisions. Although the United States Pharmacopeia takes no sides in this controversy, the backwash from it lapped at the very foundation of the authority on which rests the whole pharmacopeial program in this country.

Wisconsin Decision

A case arose which has been passed upon by the Supreme Court of Wisconsin since the date of this symposium. The validity of the Wisconsin State Pharmacy Act was challenged on the grounds that its dependence upon the United States Pharmacopeia constitutes delegation of legislative authority to a body not responsible to the Wisconsin State Legislature. In ruling against this challenge, the court quoted an 1873 Pennsylvania decision as follows:

"... the true distinction ... is this: The legislature cannot delegate its power to make a law; but it can make a law to delegate a power to determine some fact or state of things upon which the law makes, or intends to make, its own action depend. To deny this would be to stop the wheels of government. There are many things upon which wise and useful legislation must depend, which cannot be known to the law-making power and must, therefore, be a subject of inquiry and determination outside of the halls of legislation."

Another section of the act declares that a drug shall be deemed misbranded if it purports to be a drug recognized by name in an official compendium unless it is packaged and labeled as prescribed therein.

Basis of Admissions

Admissions of drugs to the National Formulary are based upon their therapeutic value, the extent of their use, or both. When therapeutic value is a consideration, admissions to the 10th edition of the National Formulary will be based on the advice and recommendations of a special committee of medical consultants.

Where extent of use is the principal criterion for admission, it is determined by a consideration of trends in drug therapy, by information obtained from prescription ingredients, by extent-of-use surveys conducted by the National Formulary and others, and by a study of drug market reports.

Prescription surveys which report results only in terms of types of drugs used in compounding and dispensing are of little significance to the Committee on National Formulary of the American Pharmaceutical Association in determining extent of use. These surveys usually report that a large percentage of the prescriptions studied are for "specialties," a small percentage are for U.S.P. drugs, and a still smaller percentage are for N.F. drugs. These reports have the added disadvantage of creating an incorrect impression about the role of the official compendiums in developing and maintaining sound standards for drugs.

Of greater service are surveys such as that by J. S. Mordell, in which the incidences of occurrence of drugs in prescriptions are recorded in terms of official names in addition to the restricted names. We all know that many official drugs are distributed under one or more trade-mark names, but they are still official drugs because in their labeling they purport to be items whose names and standards appear in the official compendiums. We sometimes forget that an official drug by any other name than an official name is still an official drug and must comply with official standards. We are finding the information in Mordell's comprehensive study useful in deciding on deletions from the ninth edition of the National Formulary.

In contrast to the basis of admissions to the National Formulary, the United States Pharmacopeia has followed a more conservative policy. In general, its scope has always been restricted to drugs selected by representatives of the medical profession and believed by them to possess the greatest therapeutic merit. Extensive duplication of drugs having essentially the same action in any single therapeutic classification has been avoided as far as feasible. This selectivity has prevented the inclusion of many drugs of therapeutic value or extensive use, or both, and is responsible for the origin and development of the National Formulary.

Two Valuable Services

The National Formulary performs a unique service by providing official standards for extensively used and therapeutically effective drugs not covered by the Pharmacopeia. It may establish specifications for widely used drugs such as rutin or vitamin E concerning the utility of which medical opinion is divided. It provides for the continuance of official standards for drugs deleted from the United States Pharmacopeia during periodic revisions. Many of these drugs continue to be used extensively for many years after losing their Pharmacopeial status. We believe the ultimate consumer is entitled to assurance of the integrity of drugs in these categories through the protection offered by official standards. During periods of shortages of critical materials used in the manufacture of dosage forms, as when glycerin was scarce during World War II, the National Formulary has been instrumental in developing official specifications for safe and satisfactory replacements.

The National Formulary also performs a distinct service to pharmacists and pharmaceutical manufacturers by providing specifications for the procurement of drugs used in dispensing, prescription-compounding, and manufacturing, and in formulas and working directions for the preparation of dosage forms.

We are conscious that the official compendiums ought to be made more useful to the practicing pharmacist. I believe this can be accomplished best by furnishing certain background information which he can use in his everyday practice. Plans have been formu-

lated for doing this in subsequent revisions of the National Formulary by the device of an appendix, the content of which cannot be construed as constituting official standards.

New and Nonofficial Remedies

By R. T. STORMONT, M.D.

The Council on Pharmacy and Chemistry of the American Medical Association was organized in 1905 to serve the medical profession by providing authoritative information about therapeutic agents.

At first the council was primarily concerned with the problem of exposing quackery in the field of therapeutics. Secret remedies, promoted under false or grossly exaggerated claims, provided a major target of attack. After the enactment of laws providing for more stringent regulatory control over drugs, the council tended to devote its efforts more toward the encouragement of a constructive program of rational therapeutics. This is reflected by the fact that the annual publication, *New and Nonofficial Remedies*, is generally regarded as the major contribution of the council toward advancing the science, if not the art, of medicine.

What is the exact nature of the information contained in *New and Nonofficial Remedies*? At present the book consists of two major divisions. The first section deals with general statements on broad classifications of preparations and monographs describing the actions, usage, and dosage of specific council-accepted drugs. The second section contains physical descriptions, tests for identity and purity, and methods of assay for the active ingredients and dosage forms of those council-accepted drugs for which official standards are not yet available. Thus, the importance of *New and Non-*

official Remedies in developing and maintaining sound drug therapy trends would appear to be self-evident. However, there are certain points which deserve some emphasis.

Physician's Guide

Nomenclature of drugs is a rather important, (though admittedly somewhat tedious, matter. The council always desires to cooperate with pharmaceutical manufacturers in the selection of generic or nonproprietary names for new drugs. The council encourages manufacturers to submit proposed generic and trade names for new products even before they are ready for the market. The early adoption of nonprotected designations for medicinal agents tends to obviate a certain amount of needless confusion in the literature. Usually such names are subsequently adopted by the United States Pharmacopeia and the National Formulary.

A drug which is accepted for inclusion in *New and Nonofficial Remedies* must be marketed and promoted in conformity with the rules of the council. The advertising and labeling must not contain claims unacceptable to the council. It is the responsibility of the drug manufacturer to submit the evidence necessary to convince the council that any proposed claims are justified.

The average physician today does not have the time or facilities to evaluate new drugs himself and to determine their proper indications for use, contraindications, limitations, and hazards. Not infrequently he finds it most difficult to study authoritative reports of the developments in therapy which are published in medical journals. He may or may not obtain reliable and useful information from a drug detail man or from promotional copy. Under these circumstances *New and Nonofficial Remedies* serves as a most useful reference volume or guide for rational therapeutics.

Some drug manufacturers and physicians have wondered why relatively few mixtures have been accepted for inclusion in *New and Nonofficial Remedies*. Obviously, it is the right and duty of a physician to know the essential composition of the drugs he prescribes. He also wishes to know if the mixtures are unnecessarily complex. He must be mindful of the fallacy of routinely prescribing unnecessarily

Dr. Stormont is secretary of the Council on Pharmacy and Chemistry of the American Medical Association, Chicago.

potent agents and of prescribing several drugs of different actions in fixed proportions in one preparation. More often than not he has to adjust the dose of a worthwhile drug to fit the therapeutic needs of the patient. The council believes that any drug should be administered according to the specific needs of the patient. Thus, a mixture containing phenobarbital and atropine in fixed proportion frequently does not serve the best interests of the patient inasmuch as he is apt to be either overdosed or underdosed with one of the active constituents.

Occasionally physicians are somewhat puzzled when an admittedly useful drug which has been on the market for a number of years does not appear in New and Nonofficial Remedies. The usual explanation is that the manufacturer has simply neglected to submit the drug to the council for acceptance. This seeming deficiency is becoming less important as firms become increasingly aware of the need and desirability of securing council acceptance for their most worthwhile products.

Modified Scope

In what respects is New and Nonofficial Remedies subject to criticism and how may it be improved? Inasmuch as the primary objective of this publication is to provide authoritative information on relatively new drugs, monographs on morphine, atropine, and the like are conspicuous by their absence. Nevertheless, it must be recognized that many old and well-known medicinal agents still have a most necessary and valuable place in our therapeutic armamentarium. An attempt will be made in future editions of New and Nonofficial Remedies to present more adequately the comparative virtues of the old and well-established official drugs in relation to the newly introduced agents. Thus, the physician should be better aided in making his choice of medication for a particular disease condition. That is one way in which New and Nonofficial Remedies can be improved and made more useful for both the physician and medical student.

Even though New and Nonofficial Remedies is revised annually, it is impossible to keep the book up to date on all developments in modern therapeutics. New drugs are being introduced with ever-increasing rapidity. One must ad-

mit that New and Nonofficial Remedies, like many other scientific treatises, is out of date in some respects immediately after publication. Nevertheless, it continues to serve a most useful purpose. Sometime in the future it may be necessary to publish New and Nonofficial Remedies at more frequent intervals. At present, however, it would appear that publication at yearly intervals should serve the needs of the physician and the medical student who also continue to study the current authoritative medical journals.

The major change in the 1953 edition, which is now in the process of revision, essentially will involve separate publication of the two major divisions of the present volume. The reason for this seemingly radical modification should be quite obvious. Physicians, medical students, and pharmacists have little or no interest in the technical detail covered in tests and standards for drugs. They depend upon manufacturers and legal regulatory agencies to insure the purity and potency of medicinal agents. It is believed that divorcing the section on tests and standards from New and Nonofficial Remedies will make the book more acceptable to the great majority of individuals who rely upon it as an authoritative guide for sound therapy.

Accepted Dental Remedies

By J. ROY DOTY, Ph.D.

It has been noted that the United States Pharmacopeia and the National Formulary at the present time primarily provide standards of identity and composition which have official recognition in the Food, Drug, and Cosmetic Act. Accepted Dental Remedies is more nearly like New and Nonofficial Remedies in that each is primarily a handbook of therapeutics and is concerned only secondarily with standards of composition. The two latter books are also similar in other respects. Both are official publications of agencies of professional associa-

Dr. Doty is secretary of the Council on Dental Therapeutics, American Dental Association, Chicago.

tions; both provide informative monographs as well as a listing of commercial products. There is also a considerable degree of similarity in the methods which are employed to determine eligibility of products for listing in New and Nonofficial Remedies and Accepted Dental Remedies. The rules of the Council on Pharmacy and Chemistry of the American Medical Association and the provisions for acceptance of products by the Council on Dental Therapeutics of the American Dental Association both emphasize the importance of suitable names, proper labeling and advertising, and the requirement of adequate evidence for the usefulness of commercial products. Each book is revised annually to provide information of current value. For each, the conclusions of the respective councils are based upon currently available information and are subject to modification at any time that a substantial amount of new evidence becomes available.

On the other hand, there are certain dissimilarities. In New and Nonofficial Remedies, the emphasis is on newness of products, whereas Accepted Dental Remedies places considerably more emphasis upon completeness of listing of drugs useful to dentists. This is possible and appears desirable in view of the fact that the number of drugs which are useful in the practice of dentistry is considerably smaller than the number which are useful in the practice of medicine. Accepted Dental Remedies even carries some informative monographs on obsolete preparations so that the dental profession may be informed concerning products described in earlier literature. However, in these instances it is clearly indicated that the listing is intended simply to provide information and that there are no products accepted in these categories.

Further differences in the books are explainable in the differences of their intended use. Since the method of use of a particular drug by a dentist may differ from its use by a physician, it does not always follow that a drug which is suitable for inclusion in New and Nonofficial Remedies will necessarily be suitable for listing in Accepted Dental Remedies.

I would like to suggest that each of the four compendiums considered in this panel discussion serves its own particular purpose and tends

to supplement the value of the others. Certainly the size and complexity of Accepted Dental Remedies would be greatly increased if official standards of composition were not available in the Pharmacopeia and the Formulary. Although the usefulness of the latter two publications might be somewhat enhanced by the suggestions presented, it is my belief that the interests of the various professions and the public will be best served by continuing their emphasis primarily on standards related to nomenclature and composition, while New and Nonofficial Remedies and Accepted Dental Remedies continue their primary emphasis on therapeutic actions and uses.

Comments on the Symposium

By LOUIS C. ZOPF, M. S.

It is generally conceded that any group of standards becomes of increasing value directly as their usefulness becomes apparent. I can subscribe to the statements which have been made in this symposium and would like to encourage the suggestions of Dr. Lloyd C. Miller and Dr. Justin L. Powers that the two official compendiums, the United States Pharmacopeia and the National Formulary, are definitely considering expanding their usefulness to the medical profession.

It is most gratifying to learn that the American Medical Association is contemplating a change in the format of New and Nonofficial Remedies by consolidating all drug standards in one section and the pharmacologic, therapeutic information in a second section.

Physicians have learned to respect the United States Pharmacopeia and the National Formulary and have also learned to understand that they are generally referred to by the abbreviations "U. S. P." and "N. F." Their understanding of these two books, however, seems to exist only as a regard for the standards for the substances listed therein and not for the knowl-

edge of the contents. They are certain that these books represent the highest standards of therapeutic requirements and are representative of considered judgment, clinical evaluation, and therapeutic merit.

It is not uncommon for a medical colleague to inquire of the pharmacist what *his* Pharmacopeia says about a specific product. The physician, while interested in the chemical and physical properties of a medicament, is primarily interested in its therapeutic use. For this reason, many of our medical colleagues find it convenient to use proprietary preparations. Commercial pharmaceutical organizations provide the physician with adequate literature to substantiate the validity of the therapeutic merits of their products.

Publicity alone is not sufficient. If we expect the medical profession to utilize the pharmacopeial drugs, we should do everything possible to assist them in the methods and possibilities of their use and application of such agents.
